DESIGN/BUILD AGREEMENT

This Agreement is made as of [■], 2005, between

ONTARIO POWER GENERATION INC., a corporation existing under the laws of Ontario (“OPG” or “Owner”),

and

STRABAG AG, a corporation existing under the laws of Austria (the “Contractor”).

RECITALS

(A) OPG owns the Sir Adam Beck generating stations 1 and 2 and the pump generating stations (the “Sir Adam Beck Generating Complex”) located in Niagara Falls, Ontario.

(B) OPG is retaining the Contractor to perform the Work in connection with the Tunnel Facility Project for the Contract Price and according to the Contract Schedule.

(C) This Agreement is a conformed document and all the terms between the Parties respecting the Project are set out in this Agreement.

For value received, the Parties agree as follows.

SECTION 1. INTERPRETATION

1.1 Definitions

In this Agreement, the following terms have the respective meanings set out below.

(a) Agreement means this design/build agreement, including any recitals, schedules, Appendices and Final Submittals, as amended or restated from time to time by an Amendment.

(b) Amendment means a written amendment agreement signed by the Parties, in the form of document attached as Appendix 1.1(b), which makes any change to this Agreement.

(c) Applicable Laws, in respect of any Person, property, transaction or event, means all applicable laws, statutes, regulations, treaties, judgments and decrees applicable to that Person, property, transaction or event at the applicable time and, whether or not having the force of law, all applicable Approvals, requirements, requests, directives, rules, guidelines, codes, standards, instructions, circulars, manuals, and policies of any Governmental Authority having or purporting to have authority over that Person, property, transaction or event at the applicable time.
(d) **Application for Payment** means the application for payment delivered by the Contractor to OPG’s Representative in accordance with Section 7.2, accompanied by completed forms of the documents set out in Appendix 1.1(d) or Appendix 7.11, as applicable.

(e) **Approvals** means any permits, licences, consents, approvals, clearances, orders, ordinances, registrations, filings or other authorizations respecting the Work or Tunnel Facility Project as may be required from any applicable Governmental Authorities or by this Agreement and, for greater certainty, includes the Environmental Assessment and the Environmental Assessment Approval, and all approvals, programs, plans, procedures and clearances required thereunder.

(f) **Business Day** means any day other than a Saturday, Sunday, New Year’s Day, Good Friday, Easter Monday, Victoria Day, Canada Day, Civic Holiday, Labour Day, Thanksgiving Day, Christmas Day and Boxing Day. Each Business Day will end at 5:00 p.m. on that day.

(g) **Community Impact Agreement** means the agreement made December 22, 1993 between The Corporation of the Regional Municipality of Niagara, the Corporation of the Town of Niagara-on-the-Lake, the Corporation of the City of Niagara Falls and Ontario Hydro.

(h) **Concept Drawings** means the drawings provided to the Contractor by OPG and listed in Appendix 1.1(h).

(i) **Confidential Information** is defined in Section 2.17(a).

(j) **Contract Price** means the total fixed amount set out on Appendix 1.1(j) to be paid by OPG under this Agreement, as amended from time to time in accordance with an Amendment.

(k) **Contract Schedule** means Appendix 1.1(k) which sets out the numbers of days and/or the dates to achieve certain milestones, including Substantial Completion and the Final Completion Date, as amended and/or restated from time to time in accordance with an Amendment.

(l) **Contractor’s Personnel** means all personnel, including the Contractor’s representative and the site manager, used by the Contractor or assisting the Contractor in the performance of the Work, including any personnel, staff, labour, employees, shareholders, directors, officers, partners, members, representatives, agents, consultants, experts and any other workers, of the Contractor or a Subcontractor, any Subcontractor who is an individual, and any other Person for whom the Contractor or any Subcontractor is responsible.

(m) **Contractor’s Proposal Documents** means the Preliminary Design and Construction Approach, the Outline Specifications, the GBR, the Draft Drawings, the Draft Specifications for the TBM, the Outline Environmental Management Plan, the Outline Quality Assurance/Quality Control Program, the Preliminary
Project Specific Site Safety, Security, Public Safety and Emergency Response Plan, the Preliminary INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan, the on-Site total monthly trade labour hours set out in Appendix 1.1(hhhh), the Acknowledgment of Labour Requirements Clause and the list of Key Personnel, all as appended to this Agreement and provided by the Contractor to OPG in response to OPG’s request for proposals for performance of the Work (which may or may not have been amended through negotiations between the Parties prior to being incorporated into this Agreement).

(n) **Defective** means:

(1) any part of the Work or Tunnel Facility Project that is defective in whole or in part, is inoperative, fails in any way to perform to specification or meet design tolerances because of any defect or does not comply with this Agreement, including any failure to comply with any requirement of the Owner’s Mandatory Requirements or any Final Submittal, reference standard, inspection, test or Approval required for the Work or otherwise referred to in this Agreement, including whether or not the non-compliance is the result of defective Work (including design, workmanship and installation); or

(2) any part of the Goods or Tunnel Facility Project that was damaged on or before the Final Completion Date (but excluding damage that was caused by OPG and occurred after Substantial Completion to a part of the Tunnel Facility Project for which OPG was responsible at the time the damage occurred).

(o) **Dispute** is defined in Section 11.1(a).

(p) **Dispute Review Board** is defined in Section 11.1(a).

(q) **Dispute Review Board Agreement** is defined in Section 11.1(a).

(r) **Preliminary Design and Construction Approach** means the design and construction approach prepared by the Contractor and set out in Appendix 1.1(r).

(s) **Draft Drawings** means the 30% complete drawings prepared by the Contractor and listed in Appendix 1.1(s).

(t) **Draft Specifications for the TBM** means the specifications prepared by the Contractor and set out in Appendix 1.1(t).

(u) **Drawings** means the drawings to be provided by the Contractor in accordance with this Agreement.

(v) **Environmental Assessment** (or EA) means the Niagara River Hydroelectric Development Environmental Assessment dated March 1991, including the update
of July 13, 1992, and the amendment of June 3, 1993, all as approved by the Environmental Assessment Approval.

(w) **Environmental Assessment Approval** (or **EA Approval**) means the environmental assessment approval, dated October 14, 1998, approved by Order in Council Number 2283/98.

(x) **Escrow Information** is defined in Section 12.1.

(y) **Final Completion Date** means the day which is the later of:

1. the day on which OPG accepts the Work as being entirely finished under Section 7.10(a);
2. the day on which the Contractor has delivered to OPG the Maintenance Bond described in Section 4.1(f); and
3. the day on which the Contractor, subject to the maximum liquidated damages set out in Section 8.5, has paid to OPG all amounts owing to OPG pursuant to Sections 8.1 and 8.3.

(z) **Final Submittal** is defined in Section 2.8(g).

(aa) **Flow Verification Test** means the test and procedures described in Appendix 1.1(aa).

(bb) **Geotechnical Baseline Report** (or **GBR**) means the geotechnical baseline report which establishes the geotechnical baseline for the anticipated subsurface conditions at the Site, a copy of which is attached as Appendix 5.4.

(cc) **Goods** means any goods, materials, instruments, devices, articles, supplies, equipment, machinery, structures and assemblies, or components of any of them, including the TBM, delivered or required to be delivered to the Site, to OPG or to such place or Person as OPG may direct, under this Agreement, whether or not incorporated into the Project.

(dd) **Governmental Authority** means any domestic or foreign government, including, any federal, provincial, state, territorial, municipal or local government, and any government established court, agency, tribunal, commission or other authority exercising or purporting to exercise executive, legislative, judicial, regulatory or administrative functions respecting government.

(ee) **Guaranteed Flow Amount** (or **GFA**) means 500 cubic meters per second (m$^3$/s) at the reference hydraulic head and the reference elevation of energy grade line defined in Appendix 1.1(aa).

(ff) **Hazardous Material** means any substance, material, solid, liquid or gas, waste (including “subject waste”, as defined in Regulation 347 under the *Environmental*
Protection Act (Ontario)) exposure to which is prohibited, limited or regulated by any Applicable Law or the Contractor’s environmental management plan.

(gg) INCW means the International Niagara Control Works Structure.

(hh) INCW Part Project means the portion of the Work that is described in Appendix 1.1(sss), Section 3.1(h) under the heading “INCW Part Project Area” and on the Concept Drawings as the “INCW Part Project Area”.

(ii) INCW Part Project Area means the area defined on the Concept Drawings.

(jj) INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan is defined in Section 2.20(d).

(kk) INTENTIONALLY DELETED.

(ll) Lien means any:

(1) lien, charge, attachment, security interest, mortgage, hypothec, claim, deemed trust or other encumbrance, whether fixed or floating, including any lien arising in respect of the Construction Lien Act (Ontario);

(2) pledge or hypothecation; or

(3) deposit arrangement, priority, conditional sale agreement or other title retention agreement, equipment trust, capital lease or other security arrangement of any kind,

respecting any property, whether real, personal or mixed, tangible or intangible.

(mm) Losses means all claims, demands, costs, penalties, expenses, liabilities, injuries, fines, losses and damages (including all fees and charges of engineers, architects, accountants, lawyers and other professionals and experts (in each case on a dollar for dollar full indemnification basis) and all court, arbitration and other dispute, mediation or resolution costs and charges), whether incurred through settlement or otherwise, together with interest at the rate equivalent to the prevailing Bank of Canada Prime Lending Rate plus 2% annually, compounded monthly, and calculated from the date that the Losses were suffered or incurred, in each case whether arising before or after the termination of this Agreement.

(nn) INTENTIONALLY DELETED.

(oo) Notice means any notice, approval, demand, direction, instruction, consent, designation, request, document, instrument, certificate or other communication required or permitted to be given under this Agreement.

(pp) OPG Group means OPG, each of OPG’s wholly-owned subsidiaries and each of OPG’s and each such subsidiary’s shareholders, directors, officers, employees,
representatives, agents and advisors, including OPG’s Representative and OPG’s Designated Delegates, but, for greater certainty, excluding the Contractor, each Subcontractor and each of the Contractor’s and each Subcontractor’s shareholders, directors, officers, partners, members, employees, representatives, agents, advisors, the Contractor’s Personnel and any other Person for whom the Contractor or any Subcontractor is responsible at law.

(qq) **OPG’s Designated Delegates** means Persons, who may or may not be employees of OPG, who have been designated, from time to time, in writing by OPG’s Representative, in a Notice in the form of document attached as Appendix 1.1(qq) as delegates of OPG, within a specified scope and limits of authority, by OPG’s Representative or are otherwise named as OPG’s delegates in this Agreement.

(rr) **OPG’s Representative** means the individual designated in writing by OPG from time to time to act as OPG’s representative for all purposes in dealings with the Contractor under this Agreement.

(ss) **Outline Environmental Management Plan** means the plan prepared by the Contractor and set out in Appendix 2.5(a)(2).

(tt) **Outline Quality Assurance/Quality Control Program** means the outline of the quality assurance and quality control program prepared by the Contractor and set out in Appendix 2.12(c)(2).

(uu) **Outline Specifications** means the specifications prepared by the Contractor and set out in Appendix 1.1(uu).

(vv) **Owner’s Mandatory Requirements** means OPG’s minimum mandatory requirements for the Work set out in Appendix 1.1(vv), as amended or restated by an Amendment from time to time.

(ww) **Party (or Parties)** means OPG and/or the Contractor together with their respective successors and permitted assigns.

(xx) **Performance LC(s)** is defined in Section 4.1(d).

(yy) **Performance Test Water Flow Amount** (or **PTWFA**) means the water flow amount determined by the water flow performance test performed in accordance with the Flow Verification Test.

.zz) **Person** means any individual, sole proprietorship, partnership, corporation or company, with or without share capital, trust, foundation, joint venture, Governmental Authority or any other incorporated or unincorporated entity or association of any nature.

 aaa) **Preliminary INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan** means the preliminary project specific site
safety, security, public safety and emergency response plan prepared by the Contractor for the INCW Part Project and set out in Appendix 2.20(d).

(bbb) INTENTIONALLY DELETED.

(ccc) Preliminary Project Specific Site Safety, Security, Public Safety and Emergency Response Plan means the preliminary project specific site safety, security, public safety and emergency plan prepared by the Contractor and set out in Appendix 2.4(d).

(ddd) INTENTIONALLY DELETED.

(eee) Professional means a licensed professional, including engineers and architects, duly licensed in Ontario, and designated by the Contractor, to provide, in whole or in part, any of the Professional Services.

(ff) Professional Services means all the services in respect of this Agreement, including respecting documents, designs, drawings (including as built drawings), diagrams, illustrations, schedules, performance charts, brochures, specifications, plans, progress photographs, reports, manuals (including operating and maintenance manuals), information, data or other deliverables, models or samples whether in a written, graphic, physical, electronic or other format provided, or required to be provided, by the Contractor to OPG under this Agreement, that are:

1. required under Applicable Laws or any Approvals to be provided by a Professional;
2. required by this Agreement to be provided by a Professional;
3. provided by a Professional retained by the Contractor, including by the Contractor’s Personnel; or
4. necessary for performance of the Work.

(gg) Project means all of the planning, approvals, design and construction elements contemplated for the diversion tunnel and associated works of which the Tunnel Facility Project forms a part.

(hh) Project Change Directive means a written directive or consent signed by OPG’s Representative, in the form of document attached as Appendix 1.1(hh).

(iii) Project Change Notice means a written notice signed by the Contractor, in the form of the document attached as Appendix 1.1(iii).

(jj) Project Specific Site Safety, Security, Public Safety and Emergency Response Plan is defined in Section 2.4(d).

(kk) INTENTIONALLY DELETED.
(lll) **Schedule of Values** is defined in Section 7.1.

(mmm) **Site** means (a) the areas identified in the Concept Drawings (including the INCW Part Project Area) and (b) all the subsurface areas where Work is performed.

(nnn) **Specifications** means the specifications to be provided by the Contractor in accordance with this Agreement.

(ooo) **Subcontractor** means a Person (including the Person’s successors and permitted assigns) who supplies Work under an agreement with the Contractor, another Subcontractor or a combination of the Contractor and another Subcontractor.

(ppp) **Submittal** means:

1. a document, design, drawing (including as built drawings), diagram, illustration, schedule, performance chart, brochure, specification, plan, progress photograph, report or manual (including operating and maintenance manuals);
2. information, data or other deliverable; or
3. model or sample,

whether in a written, graphic, physical, electronic or other format, prepared by or for the Contractor which illustrates details of a portion of the Work or is otherwise required by this Agreement, or is reasonably requested by OPG, and is to be submitted by the Contractor to OPG, or as OPG directs, under this Agreement.

(qqq) **Submittal Schedule** means the schedule of Submittals referred to in Section 2.7(a)(2) as finalized by the Contractor and submitted to OPG’s Representative in accordance with Section 2.7(a), as amended from time to time in accordance with an Amendment.

(rrr) **Substantial Completion** is defined in Section 7.9(a).

(sss) **Summary of Work** means the summary of the Work set out in Appendix 1.1(sss).

(ttt) **Start Date** means September 1, 2005.

(uuu) **Tax** means all present and future taxes, surtaxes, duties, levies, imposts, rates, fees, premiums, assessments, withholdings, dues and other charges of any nature imposed by any Governmental Authority (including income, capital (including large corporations), gross receipts, consumption, sales, use, transfer, goods and services or other value-added, excise, customs or other import, anti-dumping, countervail, net worth, alternative or add-on minimum, windfall profits, stamp, registration, franchise, payroll, employment insurance, Canada Pension Plan, workers’ compensation, health, education, school, business, property, local
improvement, environmental, development and occupation taxes) together with all fines, interest, penalties in respect thereof, or in lieu of or for non-collection thereof.

(vvv) **TBM** means the tunnel boring machine used for performing the Work.

(www) **TBM Accessories** is defined in Section 2.10(a).

(xxx) **TBM Completion Date** is defined in Section 2.10(b).

(yyy) INTENTIONALLY DELETED.

(zzz) INTENTIONALLY DELETED.

(aaaa) INTENTIONALLY DELETED.

(bbbb) INTENTIONALLY DELETED.

(cccc) INTENTIONALLY DELETED.

(dddd) INTENTIONALLY DELETED.

(eeee) **Tunnel Facility Project** means the portion of the Project which the Contractor is responsible for under this Agreement, and includes the INCW Part Project.

(ffff) **Warranty Period** is defined in Section 9.8(a).

(gggg) **Work** means providing to OPG entirely finished and fully functional tunnel diversion facilities and all associated and related facilities necessary to divert the GFA, over a distance of approximately 10.3 km from the upper Niagara River to the Sir Adam Beck Generating Complex. The Work includes providing the Goods, and a facility that is designed and constructed in accordance with, and that is fit for the purposes intended by, this Agreement, whether express or implied, including those components described in the Summary of Work attached as Appendix 1.1(sss).

(hhhh) **Man-Hour Breakdown** means the man-hour breakdown by unionized trade category and calendar month for on-Site trade labour during the term of this Agreement, to be submitted by the Contractor to OPG as a Submittal in accordance with Section 7.13(g) and consistent with the per month on-Site total trade labour hours attached hereto as Appendix 1.1(hhhh).

### 1.2 Headings and Table of Contents

The division of this Agreement into sections, the insertion of headings and the provision of a table of contents are for convenience of reference only and are not to affect the construction or interpretation of this Agreement.
1.3 Expanded Definitions

Unless otherwise specified, words importing the singular include the plural and vice versa and words importing gender include all genders. The term “including” means “including without limitation”, and the terms “include”, “includes” and “included” have similar meanings. The term “will” means “shall”. Any reference in this Agreement to any other agreement, is deemed to include a reference to that other agreement, as amended or restated from time to time. When words that have a well-known technical, construction industry or trade meaning are used in this Agreement to describe any Work, such words will be interpreted in accordance with that meaning.

1.4 Time of Day

Unless otherwise specified, references to time of day or date mean the local time or date in Niagara Falls, Ontario. When any period of time is referred to in this Agreement by days, it will be computed to exclude the first and include the last day of such period. A day is 24 hours measured from midnight to the next midnight.

1.5 Business Days

If under this Agreement any payment or calculation is to be made on or as of a day which is not a Business Day, that payment or calculation is to be made on or as of the next day that is a Business Day.

1.6 Governing Law

This Agreement and each of the documents contemplated by this Agreement are governed by, and are to be construed and interpreted in accordance with, the laws of Ontario and the laws of Canada applicable in Ontario. Each of the Parties irrevocably submits to the non-exclusive jurisdiction of the courts of Ontario. No Party will oppose the enforcement against it in any other jurisdiction of any judgment or order duly obtained from an Ontario court respecting this Agreement. A Party may effect service of summons or any other legal process that may be served in any action, suit or other proceeding by delivering any such process to another Party in accordance with Section 14.4. Nothing in this Section 1.6 will affect the rights of a Party to serve legal process in any other manner permitted by law.

1.7 Conflict

If there is a conflict between any term in one part of this Agreement and any term in another part of this Agreement, the relevant term in the part of this Agreement or other document listed first in this Section 1.7 is to prevail:

(a) Amendments, excluding any part of an Amendment that applies to an Appendix;

(b) this Agreement, excluding the Appendices and Final Submittals;

(c) the Owner’s Mandatory Requirements;
(d) the Geotechnical Baseline Report (GBR);

(e) Amendments to any other Appendix (for greater clarity, an Amendment to any Appendix other than Appendix 1.1(vv), Appendix 5.4 and the Contractor’s Proposal Documents);

(f) any other Appendix (for greater clarity an Appendix other than Appendix 1.1(vv), Appendix 5.4 and the Contractor’s Proposal Documents);

(g) Final Submittals, as amended or restated; and

(h) Contractor’s Proposal Documents.

1.8 Severability

If any term of this Agreement is or becomes illegal, invalid or unenforceable, the illegality, invalidity or unenforceability of that term will not affect the legality, validity or enforceability of the remaining terms of this Agreement and the Parties will, if necessary, amend this Agreement to accomplish the intent of the Parties as originally set out in this Agreement to the maximum extent allowed by Applicable Laws.

1.9 Time

All references in this Agreement to time are intended by the Parties to be the actual time designated without the application of any principles of equity.

1.10 Statutory and Technical References

Each reference to a statute in this Agreement is deemed to be a reference to that statute, and to the regulations made under that statute, all as amended or re-enacted from time to time. Each reference, whether express or implied, to a standard, specification, manual or code of any technical organization or Governmental Authority is deemed to be a reference to that standard, specification, manual or code as amended or re-published from time to time.

1.11 Entire Agreement

This Agreement constitutes the entire agreement between the Parties regarding the subject matter and, except for any Amendment or Project Change Directive, supersedes all other agreements, negotiations, discussions, undertakings, representations, warranties and understandings, whether written or verbal, including any OPG invitation to submit design-build proposals, any Contractor proposal and any amendments or restatements of any such request. Specifically, except as expressly provided in this Agreement, OPG has not made any representations or warranties whatsoever respecting the Tunnel Facility Project, the Project or this Agreement, including any minimum or maximum hours of employment or respecting any information previously provided to the Contractor, physical conditions, labour conditions or scheduling, including subsurface conditions.
1.12 Appendices

The following Appendices are attached to and form part of this Agreement.

</table>
SECTION 2. CONTRACTOR’S OBLIGATIONS

2.1 Intent and Initial Actions

(a) General. The Contractor will, safely and diligently, perform and complete the Work in an organized and timely manner and in accordance with this Agreement and, to the extent not inconsistent with this Agreement, good industry practices. The Contractor will ensure that all Work is performed in accordance with and complies with the Owner’s Mandatory Requirements, the Contractor’s Proposal Documents, Final Submittals, Applicable Law and the other terms of this Agreement.

(b) Bargain. This Agreement contains certain allocations of risk which reflect an informed and voluntary allocation of risk between OPG and the Contractor. This allocation represents a material part of this Agreement.

(c) Intent. The Contractor will provide all work, services and goods of any kind (which are deemed to be part of the Work), whether or not specifically required under this Agreement, which are evidently necessary, usually provided by prevailing custom or trade usage, or can be reasonably implied for the proper performance of the Work and the safe and proper operation of the Tunnel Facility Project.

(d) Acknowledgement. The Contractor acknowledges that OPG may, from time to time, have representatives present on Site or at off site locations where Goods are being manufactured or fabricated, to monitor performance of the Work and compliance with this Agreement.

(e) Representations Regarding the Tunnel Facility Project. The Contractor represents and warrants to OPG that the Contractor:

(1) is, and will, throughout the term of this Agreement, be sufficiently experienced and properly qualified, licensed, equipped, organized and financed to perform, or cause to be performed, the Work;

(2) has engaged and will engage only Subcontractors that are competent, properly qualified, licensed, equipped, organized and financed, and has made appropriate enquiries and exercised appropriate due diligence to
confirm the competence, qualification, licensing, organization and financing of the Subcontractors;

(3) has examined and has satisfied itself in respect of all matters respecting the Work and Tunnel Facility Project, including:

(A) all necessary information respecting the risks, contingencies and other circumstances which may affect the Contract Schedule, Contract Price, the Work or the Tunnel Facility Project;

(B) the nature, location and physical conditions of the Site, including, surface conditions and the location of all above and below surface buildings, utilities, structures, pipes, conduits and works except the existing tunnel routes and except to the extent such matters are addressed in the GBR;

(C) working and storage space, access, transportation, delivery and construction facilities;

(D) the general and local conditions, particularly those bearing upon labour, transportation, delivery, roads and uncertainties of weather;

(E) all Applicable Laws, including any restrictions on hours of work, and any required Approvals; and

(F) the goods, equipment and facilities needed to perform the Work.

(4) has satisfied itself that it can perform and entirely finish the Work in accordance with the Contract Schedule;

(5) has prepared the Contractor’s Proposal Documents in accordance with the degree of care and skill used by leading members of the professional engineering profession practicing in Canada and the United States for a similar type of project, in accordance with all Applicable Laws and engineering practices and industry standards and specifications as they apply to tunnel projects and in a manner that complies with the Owner’s Mandatory Requirements (including any requirements relating to the Environmental Assessment);

(6) having done all things necessary to inform itself, is not aware of any error or omission in the Owner’s Mandatory Requirements, or elsewhere in this Agreement or any inconsistency between the Owner’s Mandatory Requirements and this Agreement, between this Agreement and the Appendices, or between Appendices (and if an error, omission or inconsistency is subsequently discovered, will promptly provide a Notice to OPG of such error, omission or inconsistency);
(7) has reviewed the Owner’s Mandatory Requirements and is satisfied, based upon those requirements and the Contractor’s investigations and analyses, that upon performing the Work the water flow from the tunnel following the completion of the Tunnel Facility Project will meet the Guaranteed Flow Amount;

(8) has carefully studied all reports of explorations and tests of surface and subsurface conditions at or contiguous to the Site and all drawings of physical conditions in or relating to existing surface or subsurface structures at or contiguous to the Site which have been identified or made available by OPG;

(9) is aware of the general nature of work to be performed by OPG and others at the Site that relates to the Work;

(10) has disclosed in writing to OPG the names of each of the Contractor’s Personnel who will be performing Work at the Site continuously, who is a former OPG employee and who received a severance package from OPG, is receiving pension payments from OPG or is receiving a non-working pension bridge from OPG or is on a paid leave of absence from OPG; and

(11) is not aware of any legal action instituted, threatened or pending against the Contractor that could have a material adverse effect on its ability to perform its obligations under this Agreement.

(f) **Financial Information.** The Contractor authorizes OPG to make credit enquiries about the Contractor or any of its affiliates from time to time and to receive and exchange credit information from credit reporting agencies or other Persons with which the Contractor or any of its affiliates has or may expect to have financial dealings. The Contractor has provided OPG with the Contractor’s audited financial statements for the last three financial years. Such financial statements have been prepared in accordance with the requirements of the Austrian Commercial Code, consistently applied. Such financial statements fairly reflect the consolidated financial position and results of operations of the Contractor as at the dates and for the periods set out in such statements. The Contractor will provide OPG with its audited financial statements and unaudited quarterly consolidated financial statements promptly after each such statement becomes available. The Contractor will also provide OPG with any other financial information respecting the Contractor or any of its affiliates that OPG may reasonably request to assist OPG in its ongoing evaluation of the value of the indemnifications and other rights provided to OPG by the Contractor under this Agreement.

(g) **Information Waiver.** The Contractor acknowledges that the Contract Price was determined on the basis that some or all of the information provided by OPG may contain errors, omissions or inaccuracies and that the Contractor waives any claim arising therefrom unless the error, omission or inaccuracy was the result of gross
negligence on the part of OPG or Persons providing services to OPG, provided that nothing in this Section 2.1(g) is intended to affect the operation of Sections 5.4 and 5.5 (which are the only provisions of this Agreement governing changes in or differing geotechnical subsurface conditions).

2.2 Tunnel Facility Project Organization

(a) **Personnel.** Appendix 2.2(a) sets out an organizational chart identifying some of the Contractor’s Personnel by name, title and contact information. At OPG’s request, the Contractor will provide OPG with résumés for any such personnel indicating his or her qualifications for the performance of the Work. The names on the chart that are followed by an asterisk are considered key personnel. The Contractor will not remove any such key personnel from the performance of the Work, or materially reduce the responsibilities respecting the performance of the Work unless:

1. OPG’s Representative consents in advance in writing to such removal or reduction; or

2. any such key personnel leave the employ of the Contractor (and all its affiliates) or the applicable Subcontractor (and all its affiliates), the Contractor delivers a Notice to OPG regarding such departure.

The Contractor will replace any such key personnel with an individual who is at least equally qualified and experienced, and will update Appendix 2.2(a) to reflect such changes from time to time or at any time on request by OPG. The Contractor will obtain OPG’s consent in advance in writing to any individual who replaces any such key personnel. The names on the chart that are followed by a (1) are to be interviewed by OPG and OPG has the right to approve such Person prior to such Person being involved in any material way in performing the Work.

(b) **Site Manager.** The Contractor will keep on the Site at all times during the performance of Work on Site a competent and efficient resident site manager.

1. The Contractor will not replace this site manager unless the Contractor delivers a Notice to OPG’s Representative at least 25 days before the replacement and OPG’s Representative consents in writing to such replacement.

2. This site manager will be the Contractor’s representative at the Site and will have authority to act on behalf of the Contractor.

3. The site manager may delegate duties to superintendents, health and safety supervisors, account managers, records managers and other Persons designated by name and shown on Appendix 2.2(a) or as otherwise approved in writing by OPG.
(4) The site manager will specify in writing, in the form of document attached as Appendix 2.2(b), the scope and the limits of authority of each of his or her designated delegates.

(5) Any changes to or revocation of any delegations will also be specified by the site manager in writing to OPG’s Representative in the form of document attached as Appendix 2.2(b).

(6) All Notices delivered to the site manager, or, in OPG’s sole and absolute discretion, to his or her designated delegates (provided that the notice relates to a matter within the designated delegate’s scope of authority), by OPG will be as binding on the Contractor as if given to the Contractor under Section 14.4.

(7) OPG may rely on any written instructions, directions or approvals provided by the site manager or his or her designated delegates (provided that such instructions, directions or approvals are within the designated delegate’s scope of authority).

(8) OPG’s determination as to whether or not a matter is within the scope of authority of a designated delegate of the Contractor’s representative will be conclusive, so long as OPG has acted in good faith and does not have actual notice that the matter is not within the designated delegate’s scope of authority.

(9) The Contractor will take all reasonable steps to ensure that the site manager and all designated delegates are accessible to OPG during the performance of the Work (including outside of normal working hours in cases of emergencies) and are available to render any necessary decisions or instructions promptly to avoid delays to the Contract Schedule.

2.3 Kick-Off and Subsequent Meetings

(a) **Kick-Off Meeting.** Within 10 Business Days after the Start Date, OPG’s Representative will arrange a kick-off meeting. The Contractor will ensure attendance by its authorized representatives and any representatives of Subcontractors, including senior management, as required by OPG. At this meeting the Parties will discuss safety and environmental protection programs (including those of Subcontractors) and requirements, the hazards associated with the Work, labour matters, design concepts, schedules (including the schedules to be developed pursuant to Section 2.7), procedures for handling Submittals, communication protocols, procedures for processing each Application for Payment, delivery procedures for the Site, records maintenance, Site security, OPG’s review of Site conditions and any other matter raised by a Party.

(b) **Meetings.** In addition to the kick-off meeting, the Contractor will schedule, attend and conduct such other project readiness, pre-construction, design review, construction, pre-job mark up (including resolution of jurisdictional issues),
hazard review, site co-ordination, weekly (or daily as required by OPG) progress review meetings and other meetings as requested by OPG or are otherwise desirable, including any meetings required by the Contractor’s Proposal Documents or the Final Submittals. The Contractor will include in the agenda of any such meeting any issue requested by OPG. Progress review meetings will usually focus on safety, environmental matters, labour requirements, procedures, progress, clarifications of the requirements of this Agreement and scheduling (including interfaces between Persons providing services at the generating station). The Contractor will ensure that all Subcontractors and other Persons requested by OPG will attend these meetings. The Contractor will ensure that each representative of the Contractor and any Subcontractor attending meetings will be qualified and authorized to act on behalf of the Party each represents. The Contractor will provide the space for the meeting. Unless OPG otherwise requests regarding a particular meeting, OPG will prepare and distribute minutes of each meeting within 5 Business Days.

2.4 Safety - General

(a) **Primary Goal.** Safety of the Contractor’s Personnel, individuals at or near the Site and the public is of paramount concern to OPG. In the performance of the Work, the Contractor will not in any manner endanger the safety of, or unlawfully interfere with other Persons on or off the Site, including the public.

(b) **Constructor.** The Contractor will be the “Constructor” in respect of the Work for the purposes of the *Occupational Health and Safety Act* (Ontario). The “Constructor” will submit the required notice of project and registration form to the applicable Governmental Authority. The Contractor will have complete and sole responsibility for all health and safety matters regarding the Tunnel Facility Project. The Contractor is not required to ask OPG for any input or recommendations (and OPG may not require the Contractor to take any specified actions) respecting any health or safety matter regarding the Tunnel Facility Project. OPG will not provide to the Contractor any personnel, equipment or services. Notwithstanding any term in this Section 2.4(b), OPG may at any time on delivery of a Notice to the Contractor, assume the role of the “Constructor”.

(c) **Compliance.** The Contractor will perform all the Work in accordance with:

(1) all Applicable Laws and applicable collective agreements;

(2) and to the extent not inconsistent with Section 2.4(c)(1), the Project Specific Site Safety, Security, Public Safety and Emergency Response Plan, as described in Section 2.4(d);

(3) and to the extent not inconsistent with Sections 2.4(c)(1) and 2.4(c)(2), the Contractor’s safety program (a copy of which is attached as Appendix 2.4(c)), as amended from time to time;
and to the extent not inconsistent with Sections 2.4(c)(1), 2.4(c)(2) and 2.4(c)(3), the very best of practices respecting health and safety and in a manner that recognizes and minimizes the risks to workers, other individuals and property.

The Contractor will forward to OPG, without delay, any changes to its safety program made during the course of performing the Work. OPG will monitor the compliance of the Contractor and Subcontractors with these requirements through periodic audits from time to time during the course of the performance of the Work. The Contractor will forward to OPG, without delay, any change to the Council Amendment to Draft #7 (CAD-7) rating of the Contractor or to any Subcontractor performing Work at the Site.

(d) **Project Specific Site Safety, Security, Public Safety and Emergency Response Plan.** The Contractor has performed a safety hazard analysis to identify all significant safety hazards in respect of the Work. Based on this analysis and the Preliminary Project Specific Site Safety, Security, Public Safety and Emergency Response Plan, the Contractor will prepare, in accordance with the standards described in Section 2.8(b) and the procedures described in Section 2.8(c), a detailed project specific site safety plan (the plan, as amended from time to time, the “**Project Specific Site Safety, Security, Public Safety and Emergency Response Plan**”) which will document how the Contractor will address all significant safety hazards including the methodology for safe work planning and will include provision for the regular and systematic review and audit of the plan elements by the Contractor to determine whether the Project Specific Safety, Security, Public Safety and Emergency Response Plan requires modification to more appropriately and effectively address all safety hazards associated with the Work. The Contractor will provide for the communication of the Project Specific Site Safety, Security, Public Safety and Emergency Response Plan to all workers performing Work on the Site and all Subcontractors. The Contractor will submit the Project Specific Site Safety, Security, Public Safety and Emergency Response Plan to OPG within 30 days after the Start Date and such plan will be deemed to form part of this Agreement. The Project Specific Site Safety, Security, Public Safety and Emergency Response Plan will be implemented by the Contractor. To the extent the Contractor’s review and audit of the Project Specific Site Safety, Security, Public Safety and Emergency Response Plan reveals that the Project Specific Safety, Security, Public Safety and Emergency Response Plan requires modification to more appropriately and effectively address all safety hazards associated with the Work, the Contractor will modify the Project Specific Safety, Security, Public Safety and Emergency Response Plan within 5 days after such review and audit. The Contractor will submit to OPG the results of its regular review and audit of the Project Specific Safety, Security, Public Safety and Emergency Response Plan, including modifications thereto, within 10 days after each review and audit. OPG may monitor the compliance of the Contractor and Subcontractors with the Project Specific Site Safety, Security, Public Safety and Emergency Response Plan through periodic audits from time to time during the course of the performance of the Work.
(e) **Safety Representative.** The Contractor will provide a qualified and experienced full time health and safety representative for the Site. The Contractor will make this representative’s sole obligation the training of the Contractor’s Personnel in safety, prevention of accidents and the maintaining, reviewing and revising of safety precautions and programs. The Contractor will form a joint health and safety committee that will include representatives of the Contractor and the trades.

(f) **Safety Precautions and Remedies.**

(1) **Protection.** The Contractor will be solely responsible for initiating, maintaining, reviewing, revising and supervising all safety precautions and programs in respect of the Work. The Contractor will take all necessary precautions (including ensuring that all of the Contractor’s Personnel are equipped with, and properly use, all safeguards and personal protective equipment necessary for the performance of the Work) for the safety of, and will provide the necessary protection to prevent damage, injury or loss resulting from the performance of the Work to:

(A) each Person who is on the Site or who may otherwise be affected by the performance of the Work, including the Contractor’s Personnel and members of the public;

(B) any of the Goods, whether in storage on or off Site;

(C) the Tunnel Facility Project; and

(D) any other property on, under, over or near the Site, whether belonging to OPG or to any other Person, including buildings and other structures, facilities, fences, gates, pavements, roadways, sidewalks, walks, vegetation, utilities and underground facilities that are not designated for removal and disposal in the course of performing the Work.

(2) **Lock-Out Provisions.** The Contractor will perform all Work under applicable lock-out procedures stipulated in the *Occupational Health and Safety Act* (Ontario) ensuring that equipment being worked on is safely isolated and de-energized.

(3) **Notification of Owners.** The Contractor will promptly deliver a Notice to OPG’s Representative as the Contractor becomes aware of, and indicating the identity of, each utility, owner of underground facilities and owner of property (excluding OPG and its subsidiaries) on, under, over or near the Site that may be affected by the Work and how each such utility or owner may be affected. OPG will deliver a Notice to the Contractor confirming the identity of each such Person and the Contractor will, at OPG’s direction, deal with or co-operate with OPG in dealing with settling all issues respecting the performance of the Work, including the protection, removal, relocation or replacement of the property of any such Person.
(4) **Repair of Damage.** To the extent that any third party, such as a utility, owner of underground facilities or owner of property (excluding OPG and its subsidiaries) on, under, over or near the Site suffers or incurs any Losses to any property caused by the Contractor or a Subcontractor, the Contractor will remedy such Losses in a timely manner and at the Contractor’s expense. The Contractor will indemnify and hold harmless each member of the OPG Group, from and against all Losses suffered or incurred by a member of the OPG Group and all claims, demands, actions, suits or proceedings for Losses made against any member of the OPG Group by a third party in connection with Losses suffered or incurred to any property of such third party caused by the Contractor or a Subcontractor.

(g) **Site Security, Public Safety and Emergency Response.** The Contractor has performed a security, public safety and emergency response analysis to identify all public safety hazards associated with the Site and the Work and to identify all potential means of unauthorized access to the Site. Based on this analysis and the Preliminary Project Specific Site Safety, Security, Public Safety and Emergency Response Plan, the Contractor will prepare, in accordance with the standards described in Section 2.8(b) and the procedures described in Section 2.8(c), a project specific site security, public safety and emergency response plan. Such plan, as amended from time to time will be included in the Project Specific Site Safety, Security, Public Safety and Emergency Response Plan and will document, among other things, how the Contractor will address all significant public safety hazards and prevent unauthorized access to the Site, the matters described in Appendix 2.4(g)(3) and will include provision for the regular and systematic review and audit of the plan elements to determine whether the Project Specific Site Safety, Security, Public Safety and Emergency Response Plan requires modification. The Contractor will provide for the communication of the Project Specific Site Safety, Security, Public Safety and Emergency Response Plan to all workers performing Work on the Site and all Subcontractors. The Contractor will submit the Project Specific Site Safety, Security, Public Safety and Emergency Response Plan to OPG within 30 days after the Start Date and such plan will be deemed to form part of this Agreement. The Project Specific Site Safety, Security, Public Safety and Emergency Response Plan will be implemented by the Contractor. To the extent the Contractor’s review and audit of the Project Specific Site Safety, Security, Public Safety and Emergency Response Plan reveals that the Project Specific Site Safety, Security, Public Safety and Emergency Response Plan requires modification to more appropriately and effectively address all public safety hazards associated with the Site and the Work and/or all potential means of unauthorized access to the Site, the Contractor will modify the Project Specific Site Safety, Security, Public Safety and Emergency Response Plan within 5 days after such review and audit. The Contractor will submit to OPG the results of its regular review and audit of the Project Specific Site Safety, Security, Public Safety and Emergency Response Plan, including modifications thereto, within 10 days after each review and audit. OPG may monitor the compliance of the Contractor and Subcontractors with the Project
Specific Site Safety, Security, Public Safety and Emergency Response Plan through periodic audits from time to time during the course of the performance of the Work.

(h) **Safety Reports.** During the performance of the Work, the Contractor will provide OPG’s Representative with:

(1) a verbal report immediately of any serious incident requiring off-site medical attention or near miss incidents which do or could have resulted in the death of, or serious injury to, a worker or other Person on or off the Site or an incident which has resulted in the death of or serious injury to a worker or other Person on or off the Site;

(2) within 24 hours of an accident, construction occurrence or incident report, a copy of all accident, construction occurrence and incident reports which the Contractor, any Subcontractor, or OPG is required to submit in respect of the Work under the *Occupational Health and Safety Act* (Ontario) or the *Workplace Safety and Insurance Act, 1997* (Ontario);

(3) within 24 hours, Notice of any visits by the Ministry of Labour and copies of any reports, orders to comply, charges, stop work orders, and notices of compliance under the *Occupational Health and Safety Act* (Ontario) or other Applicable Laws;

(4) a copy of the minutes of each meeting of the joint health and safety committee; and

(5) a monthly report within ten days of each month’s end with safety statistics for the Contractor and all Subcontractors performing Work at the Site. The Contractor will include in this report, with a brief description of each incident and injury:

(A) the number of injuries resulting in a worker requiring medical aid;

(B) the number of near miss incidents which could have resulted in the death of, or serious injury to, a worker;

(C) the number of injuries resulting in a worker’s absence from one or more complete shifts;

(D) the time each worker takes off from work for each injury;

(E) the number of Ministry of Labour orders to comply; and

(F) the total number of person hours worked by the Contractor’s Personnel at the Site broken down between the Contractor and each Subcontractor.
(i) **Stop Work Orders.** Where an order to comply, stop work order or any similar order or notice respecting the Work is issued by the Construction Health and Safety Branch of the Ontario Ministry of Labour or any other Governmental Authority, such order or notice will not be grounds for any change to the Contract Schedule or any other claim for delay or compensation, except to the extent that an action of OPG or another member of the OPG Group has resulted in such order or notice. To the extent OPG or another member of the OPG Group was immediately and directly responsible for causing the underlying circumstances giving rise to such order or notice, this situation will be deemed to constitute an excusable delay for the purposes of Section 6.2(a). The Contractor will promptly deliver to OPG’s Representative a copy of any such order or notice.

(j) **Emergencies.** In emergencies affecting the safety or protection of individuals, the Work or Tunnel Facility Project or property on, under, over or near the Site, the Contractor, without the express consent of OPG, will take reasonable actions to prevent or minimize all threatened or actual damage, injury and loss. The Contractor will indemnify and hold harmless each member of the OPG Group, from and against all Losses suffered or incurred by a member of the OPG Group and all claims, demands, actions, suits or proceedings for Losses made against any member of the OPG Group by any Person, to the extent arising in respect of any emergency medical treatment provided by any member of the OPG Group to any of the Contractor’s Personnel or any invitee of the Contractor or any Subcontractor.

(k) **Requirement to Leave.** In the case of an emergency requiring the Contractor to leave the Site at the direction of OPG, the Contractor will put all equipment in a safe state in accordance with the *Occupational Health and Safety Act (Ontario)* and leave the Site in an orderly fashion pending further instructions from OPG’s Representative.

(l) **Hazard Communication Programs.** The Contractor will co-ordinate all exchanges of material safety data sheets and other hazard communication information related to the Work required to be made available to, or exchanged between or among, Persons at the Site.

(m) **Designated Substances and Other Hazardous Materials.**

1. The Contractor is solely responsible for any “designated substances” (as defined under the *Occupational Health and Safety Act (Ontario)*) brought onto the Site by it, and shall fully remove any remaining amounts prior to or upon completion of the Work. The Contractor shall also ensure that in no event will designated substances be incorporated into the permanent facilities.

2. Any other potentially hazardous materials or substances to which OPG personnel may be exposed during operation and maintenance of the
facility must be in conformance with OPG's HAZMAT approved material list.

(3) The Contractor acknowledges that prior to execution of this Agreement, OPG provided the Contractor with a list of designated substances present at the Site (a copy of which is attached as Appendix 2.4(m)), as required pursuant to the Occupational Health and Safety Act (Ontario). OPG is not aware of any other designated substances at the Site.

(n) Indemnity Relating to Safety. To the extent that the Contractor is responsible for, caused or contributed to, in whole or in part, the circumstances giving rise to a violation, charge, fine, order, direction, stop work order or other consequence pursuant to legislation applicable to worker health and safety, including the Occupational Health and Safety Act (Ontario) or its Regulations, the Contractor will indemnify and hold harmless each member of the OPG Group from and against all Losses suffered or incurred by a member of the OPG Group and from and against all claims, demands, actions, suits or any other proceedings for Losses made against any member of the OPG Group in connection with such violation, charge, fine, order, direction, stop work order or consequence.

(o) General. The provisions of this Section 2.4 shall not apply with respect to that portion of the Work required for the INCW Part Project and carried out in the INCW Part Project Area. For greater certainty, the provisions set out in Section 2.20 shall apply to the portion of the Work required for the INCW Part Project and carried out in the INCW Part Project Area.

2.5 Environment

(a) Compliance and Protection. In addition to the Contractor’s obligation to comply with all Applicable Laws, the Contractor will perform the Work in a manner that:

(1) protects health and the environment;

(2) complies with the requirements of the Environmental Assessment, the Environmental Assessment Approval, the Approvals held or to be obtained by OPG in relation to the Project, the Community Impact Agreement, and the Approvals held or to be obtained by Contractor in relation to the Project;

(3) complies with the Outline Environmental Management Plan attached as Appendix 2.5(a)(2);

(4) complies with the Contractor’s environmental management plan, which plan will be based on the Outline Environmental Management Plan, which shall be submitted as a Submittal within 60 days after the Start Date;
(5) complies with the plans, which shall be submitted to OPG as Submittals, as required by OPG to comply with the Environmental Assessment, the Environmental Assessment Approval or required by the Owner’s Mandatory Requirements;

(6) adequately anticipates, protects and plans for impacts to the environment, including spills, erosion and sedimentation, waste disposal and the use, storage and disposal of hazardous materials; and

(7) uses all commercially reasonable efforts to reduce, reuse or recycle non-hazardous waste.

(b) Notices. The Contractor will immediately provide OPG’s Representative with Notice in the form attached as Appendix 2.5(b):

(1) of any changes to its environmental management plan made during the course of performing the Work for OPG’s review and prior approval;

(2) of any discharge, spill, release, emission, deposit or leak of:

(A) fuels, oils, hydraulic fluid, herbicides; or

(B) any substance whether solid, liquid, gas, odour, heat, sound, vibration or radiation or any combination thereof, exposure to which is prohibited, limited or regulated by any Applicable Law, or the Contractor’s environmental management plan, that occur at or near the Site or that occur with the Goods or materials owned or controlled by the Contractor or a Subcontractor; and

(3) upon receipt of any order, directive, notice or other communication whatsoever received from any Governmental Authority respecting any substance whether solid, liquid, gas, odour, heat, sound, vibration or radiation or any combination thereof, exposure to which is prohibited, limited or regulated by any Applicable Law, together with a copy of such order, directive, notice or other communication.

(c) Disposal. The Contractor is responsible for the transport, receipt, inspection, use, storage and disposal of all hazardous and non-hazardous substances, materials, solids, liquids and gases that are brought on to the Site or created at the Site during performance of the Work. Without limiting the generality of the foregoing, the disposal of any excavated material produced in the performance of the Work will be carried out in accordance with:

(1) Applicable Laws;
(2) to the extent not inconsistent with Section 2.5(c)(1), the Contractor’s environmental management plan as approved by OPG, and as amended in accordance with Section 2.5(b)(1); and

(3) any order, directive, notice or other communication whatsoever received from any Governmental Authority, subject to direction by OPG’s Representative following notification in accordance with Section 2.5(b).

(d) **Discharges and Spills.** The Contractor will, to the satisfaction of all applicable Governmental Authorities and OPG, in a timely manner, at the Contractor’s expense, prevent all discharges, spills, releases, emissions, deposits or leaks contrary to:

(1) Applicable Laws; and

(2) to the extent not inconsistent with Sections 2.5(d)(1), the Contractor’s environmental management plan as approved by OPG, and as amended in accordance with Section 2.5(b)(1);

and, at the Contractor’s expense, clean up, dispose of and otherwise comply with all requirements of:

(3) Applicable Laws;

(4) to the extent not inconsistent with Section 2.5(d)(3), the Contractor’s environmental management plan as approved by OPG, and as amended in accordance with Section 2.5(b)(1); and

(5) any order, directive, notice or other communication whatsoever received from any Governmental Authority, subject to direction by OPG’s Representative following notification in Section 2.5(b);

respecting all discharges, spills, releases, emissions, deposits or leaks of any substances, materials, solids, liquids, gases or wastes whatsoever that are caused by the Contractor and that occur at or near the Site or that occur with materials owned or controlled by the Contractor.

(e) **Disposal of Hazardous Material.** Unless otherwise specifically provided for in this Agreement, the Contractor may not dispose of any Hazardous Material on, under, over or near any property owned, leased or licensed by OPG or any of its subsidiaries or in which OPG or any of its subsidiaries has an interest, in whole or in part, including the Site.

(f) **Remedy for Breach.** The Contractor will indemnify and hold harmless each member of the OPG Group from and against all Losses suffered or incurred by a member of the OPG Group and all claims, demands, actions, suits or proceedings for Losses made against any member of the OPG Group by any Person in respect
of any breach by the Contractor of any of its obligations under Sections 2.5(a) to 2.5(e) inclusive.

2.6 Applicable Laws and Approvals

(a) **Applicable Laws.** The Contractor will comply with all Applicable Laws and all applicable standards, specifications, manuals or codes of any technical organization or Governmental Authority and, to the extent not inconsistent with Applicable Laws or applicable standards, specifications, manuals or codes of any technical organization or Governmental Authority, good industry practices, in respect of the Work. Without limiting the generality of the foregoing, the TBM will comply with all Applicable Laws and all applicable standards, specifications, manuals or codes of any technical organization or Governmental Authority. OPG will not be responsible for ensuring the Contractor’s compliance with any Applicable Laws, or applicable standards, specifications, manuals or codes of any technical organization or Governmental Authority or good industry practices. Except as expressly set out in this Agreement, the Contractor will submit, and provide a copy to OPG of, all notices, requests, documents, instruments and certificates to all applicable Governmental Authorities as may be required in respect of the Work including, for greater certainty, any applications or other submissions in respect of Approvals. Notwithstanding any reference in the Contractor’s Proposal Documents to DIN or other international standards when an applicable Canadian standard exists (such as CSA), the Contractor agrees to abide by the Canadian standard.

(b) **Approvals.** Except as set out in Section 3.1(e) and 3.1(f), the Contractor will obtain and pay all the expenses in connection with all Approvals required to carry out the Work in compliance with Applicable Laws, including those Approvals to be issued in the name of OPG, in a timely manner in order to meet the Contract Schedule. For greater clarity, the identification of required Approvals shall be the responsibility of the Contractor. The Contractor will provide technical criteria, written descriptions and design data required for obtaining all such Approvals. OPG will support the Contractor as and when the Contractor requests to obtain such Approvals in order to meet the common objective of obtaining the Approvals within the expected time periods. To the extent an Approval is to be issued in the name of OPG, the Contractor will obtain OPG’s prior written approval to all terms and conditions of such Approval. The Contractor will pay all fees and other charges respecting all such Approvals obtained by the Contractor. The Contractor and the Subcontractors will comply with the terms and conditions of all Approvals. The Contractor will indemnify and hold harmless each member of the OPG Group from and against all Losses suffered or incurred by a member of the OPG Group and all claims, demands, actions, suits or proceedings for Losses made against any member of the OPG Group by any Person arising as a result of the failure of the Contractor to comply with the terms and conditions of any Approval issued in the name of OPG. The Contractor will provide a copy to OPG of all Approvals.
(c) **OPG Code of Conduct.** The Contractor will not take any action that would cause any member of the OPG Group to breach an obligation set out in OPG’s code of business conduct, as amended from time to time.

### 2.7 Schedules

(a) **Development of Schedules.** The Contractor will complete and submit to OPG’s Representative as Submittals the following documents within the following time periods:

1. within 10 days after the Start Date, a 3-month detailed schedule indicating the dates for starting (and finishing, if applicable) each component of the Work (including the INCW Part Project) to be commenced within such period;

2. within 30 days after the Start Date, a schedule to provide the Submittals, which will include at a minimum the Submittals listed in Appendix 2.8(a), setting out the dates for the Contractor to submit and finalize each Submittal. The Contractor will ensure that the Submittal Schedule provides for sufficient time for review of Submittals by OPG and for the Contractor to revise Submittals in accordance with the terms of this Agreement; and

3. within 60 days after the Start Date, a detailed contract schedule indicating the dates for starting and entirely finishing each component of the Work (including the INCW Part Project), including a reference to each milestone set out in the Contract Schedule and Submittal Schedule so that this contract schedule incorporates, and integrates with, the Contract Schedule and Submittal Schedule.

OPG will review these schedules within 10 Business Days after receipt and provide the Contractor with a Notice setting out any comments on these schedules. The Contractor will then have 5 Business Days from the receipt of such Notice to respond to OPG’s comments and make any necessary amendments to these schedules. At least 20 Business Days before submission of the first Application for Payment, the parties will meet with all appropriate Persons, including OPG’s Representative, to review the status of and attempt to resolve any outstanding issues regarding these schedules. Except for the first three monthly payments made under Section 7.3, which payments shall be contingent upon agreement of the schedule described in Section 2.7(a)(1) above, OPG will make no payment to the Contractor until OPG’s review is complete, issues have been resolved and the final schedules have been delivered to OPG.

(b) **Initially Acceptable Schedules.** Any review, comment, acceptance, rejection or failure to review, comment, accept or reject by OPG of the schedules referred to in Section 2.7(a), in whole or in part, will not:
(1) impose on OPG responsibility for the sequencing, scheduling or progress of the Work;

(2) be deemed to confirm that any schedule is a reasonable plan for performing the Work in accordance with the detailed contract schedule;

(3) affect or change the Contractor’s obligation to perform the Work in accordance with this Agreement; or

(4) otherwise have the effect of transferring any obligation under this Agreement from the Contractor to OPG or otherwise have the effect of amending this Agreement.

(c) Adherence to Schedules. The Contractor will adhere to the Contract Schedule. The Contractor will provide OPG with a monthly progress schedule, setting out the status and progress of the Work and any deviations or anticipated deviations from the Contract Schedule or the detailed contract schedule described in Section 2.7(a)(3). To the extent that the Contract Schedule has not been, or is anticipated not to be, satisfied, the Contractor will indicate the total number of days set aside for contingencies that will be used and will provide OPG with satisfactory assurances, including, at the Contractor’s cost, recovery plans, involving all necessary additional resources, acceptable to OPG, that the Contract Schedule will be restored. There will be no changes to the Contract Schedule except as provided by Section 5 and Section 6 of this Agreement. OPG may refuse to approve any changes to the Contract Schedule in its sole and absolute discretion.

(d) Daily Record. The Contractor will maintain a detailed daily record of the progress of the Work, the number of personnel of all categories at the Site, the Goods delivered to the Site and all such other items deemed necessary to record.

(e) Continuing the Work. Notwithstanding any term in this Agreement, the Contractor will not stop or delay the performance of Work, in whole or in part, on account of any Dispute or pending resolution of any such Dispute between the Contractor and OPG or between the Contractor and any other Person and will continue to perform the Work in a timely manner and continue to adhere to the Contract Schedule, except to the extent, if any, expressly directed to do so by OPG in a Project Change Directive, provided that the Contractor may suspend the performance of the Work, if OPG has not paid the amounts required under Section 7.3(b) within 30 days of the date OPG is required to make payment under Section 7.3(b).

2.8 Submittals

(a) Submission of Submittals. The Contractor agrees to provide each Submittal described in Appendix 2.8(a), in addition to other Submittals as required pursuant to this Agreement all in accordance with the requirements set out in Appendix 2.8(a). The Contractor agrees to provide each Submittal to OPG (as set
(b) **Submittals Prepared by Professionals.** The Contractor will prepare the Submittals required to be prepared by a Professional, including the Drawings and Specifications as more fully described in Appendix 2.8(a), in accordance with the degree of care and skill used by leading members of the professional engineering profession practicing in Canada and the United States for a similar type of project, in accordance with all Applicable Laws and engineering practices and industry standards and specifications as they apply to tunnel projects and in a manner that complies with the Owner’s Mandatory Requirements (including any requirements relating to the Environmental Assessment and EA Approval) and the Contractor’s Proposal Documents.

(c) **Review of Submittals.** The Contractor will review and approve all Submittals before submission to OPG. The Contractor’s review and approval of each Submittal will be indicated by stamp, seal (if applicable), date and a signature of a responsible and qualified Person. Any Submittals not stamped, sealed (if applicable), signed, dated and identified may be returned to the Contractor without being examined and will be considered not to have been submitted. By this review and approval, the Contractor will be deemed to represent to OPG that it has diligently determined and verified all necessary requirements including field measurements, field construction criteria, materials, catalogue numbers and similar data and has checked and coordinated all Submittals with the requirements of the Contractor’s Proposal Documents and the remainder of this Agreement and that OPG can and will rely upon this deemed representation. Together with any Submittal, the Contractor will notify OPG’s Representative of, and clearly show or describe, any deviation of that Submittal from any requirement under this Agreement.

(d) **Return of Submittals.** OPG’s Representative will return Submittals to the Contractor marked “Reviewed as Submitted”, “Revise as Noted - Do not Resubmit”, “Revise and Resubmit” or “Review not Required”. However, if OPG, acting reasonably, determines that a Submittal is not suitable for review and does not meet the basic requirements for such Submittal, the Submittal will be returned to the Contractor and the time period for review of such Submittal by OPG pursuant to the Submittal Schedule will be deemed not to have commenced.

(e) **Non-Compliance.** The Contractor will respond, in a timely manner, to queries from OPG’s Representative respecting its review of the Submittals and provide, in a timely manner, all such other documentation and information requested by OPG’s Representative to finish its review of the Submittals. Where any Submittal delivered by the Contractor deviates from the requirements of this Agreement, OPG’s Representative may require the Contractor to conform that Submittal to the requirements of this Agreement. Unless otherwise directed by
OPG’s Representative, the Contractor will promptly, and in any event within the
time period required by the Contract Schedule and the detailed contract schedule
described in Section 2.7(a)(3), correct all items in a Submittal, whether or not
raised by OPG’s Representative, which do not conform to the requirements of this
Agreement. The Contractor will then return to OPG’s Representative the required
number of corrected copies of the Submittal clearly identifying any revisions to
the Submittal and such Submittal will continue to be subject to this Section 2.8(e)
until there is no requirement to resubmit. The Contractor will be responsible for
recovering any time lost in the review process by reason of error or defect in the
Submittals and, in any event, the Contractor will maintain the dates set out in the
Contract Schedule. If the Parties dispute the conformity of a Submittal and it is
subsequently determined by the Parties or through dispute resolution under
Section 11 that the Submittal was in conformity with the Agreement, any delay
attributable to such dispute will be treated as a delay caused by OPG pursuant to
Section 6.2(c).

(f) **Work Before Review by OPG.** Where a Submittal is required by this
Agreement including the Submittal Schedule, any Work relating to that Submittal
which is performed before OPG’s Representative has completed its review of the
Submittal (including any required revisions to the Submittal) will be at the sole
risk, responsibility and expense of the Contractor.

(g) **Effect of Review.** Notwithstanding any term of this Agreement, if OPG reviews,
comments on, accepts or rejects or fails to review, comment on, accept or reject
any Submittal or any item in a Submittal, any such action or failure to act:

1. will not have the effect of transferring any obligation under this
   Agreement from the Contractor to OPG or otherwise have the effect of
   amending this Agreement; and

2. will not affect or change in any way,

   A) the Contractor’s obligation to entirely finish the Work, or

   B) the Contractor’s responsibility for any error or omission in any
      Submittal or any deviation in a Submittal from the requirements of
      this Agreement, unless in each case OPG’s Representative gives
      express written acceptance of the error, omission or deviation.

Review of Submittals by OPG’s Representative will be for conformity to
the Contractor’s Proposal Documents, the Owner’s Mandatory
Requirements and this Agreement and for general arrangement only. In
addition, any such review will generally not extend to means, methods,
techniques, sequences or procedures of construction or to related safety
precautions or programs, other than for compliance with this Agreement
(for example, with respect to the INCW Part Project), and will not indicate
OPG’s approval of such item or OPG’s acceptance or approval of the
assembly in which the item in the Submittal functions. Once a Submittal is reviewed by OPG’s Representative and no longer requires revision, or once a Submittal is submitted where such Submittal does not require OPG’s review, such Submittal will become a “Final Submittal” and will be deemed to be incorporated into this Agreement.

(h) **Manuals.** All manuals will be in sufficient detail for OPG to operate, maintain, commission, refurbish, replace and alter the Tunnel Facility Project.

2.9 **Professional Services**

(a) **Provision.** The Contractor will provide all the Professional Services necessary or desirable to perform the Work, including all design required for a tunnel that delivers the Guaranteed Flow Amount. The Contractor will ensure that all Work is designed in accordance with Applicable Laws.

(b) **Standard of Care.** The Contractor will provide all the Professional Services necessary or desirable to entirely finish the Work and Tunnel Facility Project. The standard of care used for all the Professional Services provided under this Agreement will be the degree of care and skill used by leading members of the profession practicing in Canada and the United States for a similar type project and in accordance with all Applicable Laws, prudent practices and professional practices and industry standards and specifications as they apply to tunnel projects.

(c) **Error in Contractor’s Proposal Documents or Final Submittals.** The Contractor will promptly provide Notice, in the form of document attached as Appendix 2.9(c), to OPG’s Representative of any error, deficiency, defect, inconsistency, discrepancy, omission or deviation from the requirements of this Agreement or the Owner’s Mandatory Requirements in the Contractor’s Proposal Documents or the Final Submittals of which the Contractor becomes aware. After the Contractor provides OPG’s Representative with all information reasonably requested by it, OPG’s Representative will discuss the error, deficiency (excluding those related to health and/or safety, except for the INCW Part Project), defect, inconsistency, discrepancy, omission or deviation and provide a prompt direction to the Contractor resolving the issue by way of a Project Change Directive. If the Contractor’s Proposal Documents or the Final Submittals, or any portion of them, are found to be in error, deficient, defective, inconsistent, incomplete or deviate from the requirements of this Agreement or the Owner’s Mandatory Requirements in any way, the Contractor will perform, at its cost, having regard to the terms of this Agreement and prudent practices, any corrective work to remedy the erroneous, deficient, defective, inconsistent or incomplete part of the Contractor’s Proposal Documents or the Final Submittals and take any other remedial action with respect to the Work arising in respect of such error, deficiency, defect, inconsistency, discrepancy, omission or deviation, unless the error, deficiency, defect, inconsistency, discrepancy, omission or deviation in the Contractor’s Proposal Documents or the Final Submittals is as a result of an error
in the Owner’s Mandatory Requirements. All Work performed after the Contractor became aware of the error, deficiency, defect, inconsistency, discrepancy, omission or deviation from the requirements of this Agreement will be at the Contractor’s sole risk until OPG’s Representative makes a decision as to how to reconcile or fix the error, deficiency, defect, inconsistency, discrepancy, omission or deviation. If the Contractor fails to so provide Notice to OPG’s Representative under this Section 2.9(c) respecting any such error, deficiency, defect, inconsistency, discrepancy, omission or deviation, the Contractor may not make any claim whatsoever against OPG respecting or resulting from such error, deficiency, defect, inconsistency, discrepancy, omission or deviation.

2.10 Tunnel Boring Machine

(a) Transfer of Title to OPG. Notwithstanding any other provision of this Agreement, the Contractor hereby transfers to OPG all of the Contractor’s right, title and interest in and to the TBM, all trailing gear and tunnel transportation systems (collectively, the “TBM Accessories”) and any right, title or interest in and to the TBM and the TBM Accessories that it may acquire hereafter, free and clear of all Liens. The transfer of title to the TBM and TBM Accessories shall in no way detract from the Contractor’s obligations in Section 2.12(a).

(b) License to Contractor. OPG hereby grants the Contractor a license to the use of the TBM and the TBM Accessories for all purposes that the Contractor deems necessary to perform the Work and complete the Tunnel Facility Project, which license will terminate on the date on which all of the Work to be performed by the TBM and the TBM Accessories to complete the Tunnel Facility Project has been completed in accordance with the requirements of this Agreement (the “TBM Completion Date”).

(c) Maintenance and Repair. The Contractor shall be responsible for the maintenance, repair and refurbishment of the TBM and the TBM Accessories and any costs, charges, liabilities or expenses related thereto or incurred in connection therewith and OPG shall have no liability in respect thereof or in any way related thereto.

(d) Transfer of Title to Contractor. On the earlier of

(1) the TBM Completion Date; and

(2) the date for transfer set out in a written Notice from OPG to the Contractor which written Notice states that OPG will be transferring, conveying and assigning the TBM and the TBM Accessories to the Contractor,

OPG will be deemed to have transferred, conveyed and assigned to the Contractor all of OPG’s right, title and interest in the TBM and the TBM Accessories. For greater certainty, all costs, charges, liabilities or expenses related to or incurred in
connection with decommissioning or dismantling the TBM and the TBM Accessories shall be for the account of the Contractor.

(e) **Assignment Agreement.** The Contractor will enter into an assignment agreement in form and substance satisfactory to OPG, acting reasonably, which will assign to OPG, as security for the performance of the obligations of the Contractor hereunder, all rights, benefits and entitlements under any agreement with a Subcontractor relating to the TBM and the TBM Accessories (the “TBM Agreement(s)”) and will obtain any consents from third parties necessary in connection with such assignment.

(f) **Creditors of the Contractor.** The Contractor will require any creditor of the Contractor having or purporting to have any Lien respecting the TBM and the TBM Accessories to enter into an acknowledgement, in form and substance satisfactory to OPG, acting reasonably, which will acknowledge OPG’s interest in the TBM and the TBM Accessories.

(g) **Further Assurances.** The Contractor covenants and agrees to do such acts and enter into such agreements and other documents as OPG may reasonably require to preserve, protect and perfect OPG’s interest in the TBM, the TBM Accessories and the TBM Agreement(s).

2.11 **Commissioning and Completion**

(a) **Commissioning Phase.** During the commissioning phase of the Work as set out in the detailed contract schedule, the Contractor will

1. be responsible for the testing, verification, calibrating, refining, adjusting and watering-up of all mechanical or electrical elements, equipment or systems in the presence of OPG’s personnel, to ensure that installation and performance are as specified in this Agreement and suitable for use by OPG;

2. demonstrate operation of equipment and systems for the Tunnel Facility Project and train OPG’s staff to operate and maintain the Tunnel Facility Project;

3. develop systems and procedures for use by OPG in the control of the operation and maintenance of, and record keeping for, the Tunnel Facility Project; and

4. provide manufacturers’ authorized representatives, specialists and/or representatives of Subcontractors as may be required by OPG for the Work.

(b) **Demonstrations.** The Contractor will, before any demonstrations, inspect and put into operation all equipment and systems in accordance with the Final Submittals and this Agreement; perform testing, adjusting and balancing; ensure
equipment and systems are fully operational; and provide to OPG copies of completed operation and maintenance manuals for use in demonstrations. The Contractor will submit a schedule, for OPG’s approval, with the time and date for the demonstration of each item of equipment and each system, with a list of all personnel to be present, not more than one month and not less than two weeks before designated dates.

(c) **Post Substantial Completion Date.** Commencing on Substantial Completion, the Contractor will provide to OPG at the Site a representative, qualified to operate the Tunnel Facility Project, at all reasonable times. The Contractor will cause this representative to advise OPG in respect of the operation of the Tunnel Facility Project. The Contractor will provide this representative for a reasonable period satisfactory to OPG’s Representative, such period not to be less than one week. During such period, the Contractor’s representative will not make, or direct the making of, any change or adjustment to any part of the Goods or Tunnel Facility Project without the prior written approval of OPG’s Representative.

2.12 **Procurement**

(a) **Goods.** Except to the extent otherwise expressly provided in this Agreement, the Contractor will be responsible, at its cost, for manufacturing or supplying or procuring, factory testing, transporting, delivering, inspecting, receiving and installing all Goods, and providing all construction equipment, tools, transportation, fuel, construction and start-up power, air, light, heat, communications, water (including potable water), sewer connections and temporary structures and facilities, including for offices, lunchrooms, canteens, sanitation, showers, change rooms, accommodations, shops, warehouses and garbage disposal, and all other goods and services reasonably required in respect of the Work. The Contractor will maintain all construction equipment, tools and such temporary structures and facilities in good working order. The Contractor will conduct all these activities in accordance with this Agreement. The Contractor will maintain absolute control over, and exclusive responsibility for, the Contractor’s own, and each Subcontractor’s own, operations and the Contractor’s Personnel.

(b) **Warranty on Goods.** The Contractor will ensure that all Goods will be fit for the purposes intended by this Agreement, new, unused, not Defective and free from all Liens, of good quality and comply with all requirements under this Agreement. All warranties and guarantees set out in this Agreement are for the benefit of OPG. If required by OPG, the Contractor will provide satisfactory evidence (including reports of required inspections, tests and approvals) as to the kind and quality of all Goods. The Contractor will ensure that all Goods will be constructed, applied, assembled, erected, installed, used, connected, adjusted, field tested, conditioned, cleaned, commissioned and cleaned up in accordance with instructions of the applicable Subcontractor, except to the extent as may otherwise be provided in this Agreement.
(c) Quality Assurance.

(1) Quality Assurance Program. The Contractor will submit a quality assurance program for review to OPG as a Submittal within 60 days after the Start Date which program will be based on the Outline Quality Assurance/Quality Control Program attached hereto as Appendix 2.12(c)(2). Once accepted as a Final Submittal pursuant to Section 2.8(g), such quality assurance program will be deemed to form part of this Agreement, and will be implemented by the Contractor. The quality assurance program of the Contractor will accord with the Contractor’s own internal program and the other requirements, if any, set out in this Agreement. If there are any conflicts between the Contractor’s internal program and this Agreement, this Agreement will prevail. Compliance with these quality assurance requirements will not relieve the Contractor of any of its obligations or liabilities under this Agreement. The Contractor will ensure that all of the Work is provided in accordance with the applicable quality assurance program. OPG may have any aspect of the quality assurance program of the Contractor reviewed by any auditors designated by OPG. The Contractor will, at its expense, provide such auditors prompt access to all premises and documents required for such review.

(2) Independent Inspection Agencies. OPG may engage independent inspection or testing agencies for the purpose of inspecting and testing the quality of portions of the Work. The engagement of independent inspection or testing agencies by OPG will not relieve the Contractor of any of its obligations or liabilities under this Agreement. If the Work or the Tunnel Facility Project, in whole or in part, is found to be Defective during inspection or testing, the appointed agency will request additional inspection or testing to ascertain the full degree of the Defect. The Contractor will promptly correct Defective Work in accordance with Sections 9.7 and 9.8. The Contractor shall submit such samples and materials required for testing as may be reasonably required by OPG. The Contractor will submit such samples and/or materials with reasonable promptness and in an orderly sequence so as not to cause delay in the Work. The Contractor will provide labour and facilities to obtain and handle samples and materials on Site and shall provide sufficient space to store and cure test samples.

(3) Quality Documents. The Contractor will provide OPG with signed and dated legible copies or originals of all inspection documents pertaining to the Work, including installation and testing. The Contractor will retain all quality assurance documentation and records for seven years after the Final Completion Date or for any longer period specified in the Contractor’s Proposal Documents or the Final Submittals.
(4) **Effects of Non-Conformance.** If the Contractor identifies anything which does not conform to the quality assurance program set out in Section 2.12(c)(1), the Contractor will promptly correct such non-conformance (unless the Contractor proposes to “use as is”) and deliver a Notice in the form of Appendix 2.12(c)(4) to OPG’s Representative reporting the corrective action taken by the Contractor or that the Contractor proposes to “use as is”. OPG’s Representative will return the Notice in the form of Appendix 2.12(c)(4) to the Contractor indicating OPG’s agreement with the proposed disposition (with or without additional terms detailed in Appendix B to the Notice) or directing the Contractor to comply with the Contractor’s Proposal Documents or the Final Submittals, as the case may be.

2.13 **Construction**

(a) **Direction and Competent Supervision.** The Contractor will perform (including all direction, supervision and inspection of) the Work competently and efficiently, devoting such attention and applying such skills and expertise as may be necessary to perform the Work in accordance with this Agreement. The Contractor will at all times maintain good discipline and order at the Site. The Contractor will be solely responsible for the means, methods, techniques, sequences and procedures used to perform the Work (except with respect to the INCW Part Project, in which case OPG will be the “constructor” and will have the control necessary to effectively carry out that role, as described more particularly in Section 2.20). The Contractor will keep OPG advised as to the quality and progress of the Work and the Tunnel Facility Project in such manner and at such times as OPG may request from time to time.

(b) **Temporary Structures and Facilities.** Except with respect to the INCW Part Project (as discussed on Section 2.20), the Contractor will have the sole responsibility for:

1. the design, erection, operation, maintenance and removal of all temporary structures and facilities at the Site; and

2. the design and execution of construction methods required in the use of such structures and facilities.

(c) **Time for Performance of the Work.** The Contractor may perform the Work at any time except to the extent that performing the Work is prohibited or restricted:

1. by Applicable Laws;

2. by the Approvals;

3. in the Summary of Work; or

4. elsewhere in this Agreement.
(d) **Control Monuments.** The Contractor will establish the lay out for the Tunnel Facility Project and will maintain and protect the control monuments established by OPG. The Contractor will ensure that such control monuments are not changed or relocated without the prior written consent of OPG’s Representative. The Contractor will promptly report to OPG’s Representative whenever any control monuments are lost or destroyed or require relocation because of necessary changes in grades or locations. If OPG’s Representative provides consent to any change to, or relocation of, a control monument, the Contractor will cause such change or relocation to be carried out accurately by professionally qualified individuals.

(e) **Survey Verification.** OPG may periodically review the survey and setting out of the Tunnel Facility Project and calculations conducted by the Contractor, and will promptly provide the results of such reviews to the Contractor. In the event of discrepancy, the Contractor and OPG will collaborate to resolve the discrepancy. Unless otherwise directed by OPG in writing, successive setting out operations, that depend on previous work, shall not proceed until the discrepancy has been resolved.

(f) **Non-Compliance.** If the Contractor becomes aware of any Work which does not comply with any of the Owner’s Mandatory Requirements, the Contractor’s Proposal Documents, the Final Submittals or any provision of this Agreement, the Contractor will promptly correct such non-compliance (unless the Contractor proposes to “use as is”) and deliver a Notice in the form of Appendix 2.13(f) to OPG’s Representative reporting the corrective action taken by the Contractor or that the Contractor proposes to “use as is”. OPG’s Representative will return the Notice in the form of Appendix 2.13(f) to the Contractor indicating OPG’s agreement with the proposed disposition (with or without additional terms detailed in Appendix B to the Notice) or directing the Contractor to comply with the Owner’s Mandatory Requirements, the Contractor’s Proposal Documents, the Final Submittals or any provision of this Agreement, as the case may be.

### 2.14 Labour and Subcontractors

(a) **Competent Workers.** The Contractor will ensure all of the Contractor’s Personnel assigned to the Work or the Site, including any site manager and his or her delegates,

1. are qualified because of knowledge, training and experience to organize the Work and perform the Work;
2. are familiar with the *Occupational Health and Safety Act* (Ontario) provisions that apply to the Work;
3. understand, and have the necessary skills to perform, their roles and obligations under this Agreement including those relating to safety, the
environment, quality assurance, labour requirements, and Site rules and procedures; and

(4) have knowledge of any potential or actual danger to health or safety in the workplace and the plans and programs in place to address such danger.

(b) **Contractor Fully Responsible for Workers and Subcontractors.** The Contractor will be solely responsible for providing, scheduling and coordinating the Subcontractors and the Contractor’s Personnel unless otherwise provided in this Agreement. The Contractor will cooperate with other Persons in all matters of common interest pertaining to services being provided under agreements between OPG and such other Persons, and ensure that the Work being performed on the Site does not obstruct the operations of OPG or other Persons providing services at or near the Site. Except where OPG’s Representative requests in writing a specified form of communication, the Contractor will communicate with OPG and all such other Persons solely through OPG’s Representative. Except where OPG’s Representative requests in writing a specified form of communication, the Contractor will ensure that all Subcontractors communicate with OPG solely through the Contractor. The Contractor will be fully responsible for all acts and omissions of each member of the Contractor’s Personnel and each of the Subcontractors and any such acts and omissions will be deemed to be those of the Contractor. Accordingly, respecting each obligation of the Contractor under this Agreement, the Contractor will ensure that no worker of the Contractor, no Subcontractor and no worker of any Subcontractor will breach any such obligation. In addition, respecting each action which the Contractor is not permitted to take under this Agreement, the Contractor will ensure that no worker of the Contractor, no Subcontractor and no worker of any Subcontractor will take any such action that is not permitted. Where any Subcontractor performs any of the Work, the Contractor will ensure that the Subcontractor names OPG as a beneficiary/obligee under any performance, labour and material payment or lien bond posted in respect of that Work.

(c) **Identity of Subcontractors.** Set out in Appendix 2.14(c) is a list of each Subcontractor performing any of the Work. Where the value of all contracts with a Subcontractor exceeds 1% of the Contract Price (a “Major Subcontractor”), Appendix 2.14(c) also includes a summary of the Work to be performed by each such Subcontractor. OPG reserves the right to require the Contractor to provide such information with respect to any Subcontractor. The Contractor will not:

(1) change any such Major Subcontractor;

(2) change in a material manner the Work performed by any Major Subcontractor; or

(3) add any new Subcontractor who will be performing any Work where the value of all contracts with such new Subcontractor exceeds 1% of the Contract Price,
unless OPG’s Representative consents, in advance, in writing to such change or addition.

(d) **Subcontracts.** The Contractor will ensure that all Subcontractors and all Contractor’s Personnel comply with the terms of this Agreement as are applicable to them, including the terms relating to safety, environment, quality assurance, labour requirements and Site rules and procedures. The Contractor will enter into a written contract with each Subcontractor performing any of the Work that specifically binds the Subcontractor to the applicable terms of this Agreement, including the terms relating to safety, environment, quality assurance, labour requirements, and Site rules and procedures and this Section 2.14, for the benefit of OPG. The Contractor will ensure that each such contract contains a term stating: “Notwithstanding any term in this Agreement, the parties commit to each other and to Ontario Power Generation Inc. that each Party will comply in all respects with Section 2.14(d) of the Design/Build Agreement dated as of [insert date] between Ontario Power Generation Inc. and Strabag AG.” The Contractor will ensure that each contract with a Subcontractor respecting the Work or Tunnel Facility Project will give OPG the right to continue the contract with the Subcontractor in the place of the Contractor if OPG decides to entirely finish the Work in accordance with Section 9.8(c) or 10.3. In the case of assumption of a subcontract by OPG, all invoices submitted by the Subcontractor will be in the name of OPG. At the request of OPG, the Contractor will provide unpriced copies of any subcontract (or evidence otherwise acceptable to OPG that such subcontract complies with this Section 2.14(d)). Notwithstanding the foregoing, the Contractor will provide unpriced copies to OPG of any subcontract with the manufacturer of the TBM.

(e) **Labour Obligations.** The Contractor will comply with all obligations set out in Appendix 2.14(e) including those set out in the “Labour Requirements Clause - Form 1” attached to Appendix 2.14(e). The Contractor will indemnify and save harmless all members of the OPG Group from and against any and all Losses suffered or incurred by any member of the OPG Group on account of claims made or grievances filed by any unions on account of any breach by the Contractor or any Subcontractor of the obligations set out in Appendix 2.14(e) in the course of performing the Work or on account of other non-unionized labourers performing portions of the Work.

(f) **WSIB.** The Contractor shall submit as a Submittal the Contractor’s Workplace Safety and Insurance Board account number promptly after the account number has been obtained. The Contractor will be and remain at all times in good standing with the Workplace Safety and Insurance Board. Upon initial arrival on the Site, and from time to time at the request of OPG, the Contractor will submit a certificate of compliance from the Workplace Safety and Insurance Board as to the Contractor’s status and that of all Subcontractors that will be performing Work at the Site. Together with the certificate, the Contractor will submit a list of the Workplace Safety and Insurance Board registration numbers of each of the
Contractor’s Personnel who will be employed at the Site, and will thereafter update the list as the Work progresses.

(g) **Foreign Nationals.** The Contractor will be solely responsible for taking all necessary steps and actions to obtain at its cost all Approvals from all applicable Governmental Authorities respecting all foreign nationals who may be engaged in performing the Work in Canada.

(h) **Reasonable Objections by OPG.** The Contractor will not use, as part of the Contractor’s Personnel, any individual against whom OPG has a reasonable objection. The Contractor will promptly remove from the Site any such Person whom OPG’s Representative does not consider competent or otherwise considers unsuitable for performing the applicable Work, including for failure to comply with any applicable health or safety obligations or any other obligations under this Agreement.

(i) **Payment of Subcontractors.** The Contractor will pay in a timely manner all costs (including Taxes) respecting Work performed or caused to be performed by a Subcontractor on the Site which could result in any Lien being filed under the *Construction Lien Act* (Ontario) or otherwise against any property owned, leased or licensed by OPG or any of its subsidiaries or in which OPG or any of its subsidiaries has an interest, in whole or in part, including the Site. If the Contractor fails to make, any such payment in a timely manner, OPG may make payment directly to the applicable Subcontractor. At the request of OPG, the Contractor will cause the Subcontractor to issue any unpaid invoice directly to OPG. Section 7.5(e) will apply in respect of any such payment and the Subcontractor will be deemed to be the Contractor in respect of any applicable withholdings by OPG under Section 7.5(e). Where OPG makes any such payment, OPG may set off the full amount of any such payment against any amount otherwise owing by OPG to the Contractor.

(j) **Liens.** The Contractor will keep title to the Site and every part of the Site free and clear of all Liens respecting the performance of the Work. The Contractor will indemnify and hold harmless each member of the OPG Group from and against all Losses suffered or incurred by a member of the OPG Group from and against all Losses suffered or incurred by a member of the OPG Group by any Person in respect of any Liens registered against any property owned, leased or licensed by OPG or any of its subsidiaries or in which OPG or any of its subsidiaries has an interest, in whole or in part, including the Site. The Contractor will immediately notify OPG of any such Lien, claim of Lien or other action of which it has knowledge and which affects the title to any property owned, leased or licensed by OPG or any of its subsidiaries or in which OPG or any of its subsidiaries has an interest, in whole or in part, including the Site. If any Lien is registered against any such property, in whole or in part, including the Site, by a Subcontractor, the Contractor will cause the Lien to be vacated or discharged from title within 10 Business Days of registration. If the Contractor fails to vacate or discharge any such Lien in a
timely manner, OPG may vacate or discharge that Lien by paying into court any sum or providing such security as may be necessary to vacate or discharge the Lien. In addition, the Contractor will immediately reimburse OPG on demand for all OPG’s costs and expenses respecting the discharge, including the amount of the payment into court, the cost of any such security, OPG’s legal fees and expenses and a reasonable charge for time spent by OPG personnel. OPG may set off the full amount of any such reimbursement obligation against any amount otherwise owing by OPG to the Contractor.

(k) **Local Community.** The Contractor will use its best efforts to provide opportunities to local residents to work on the Tunnel Facility Project and to acquire goods and services necessary in regard to the Tunnel Facility Project, including construction material and aggregate, from within the Regional Municipality of Niagara, all as more particularly described in the Community Impact Agreement. The Contractor will ensure that local contractors are provided with information about the Tunnel Facility Project and its labour requirements, and will be provided with timely bidding opportunities, all as more particularly described in the Community Impact Agreement.

2.15 Use of Site and Other Areas

(a) **Documents to be Maintained on Site.** The Contractor will maintain in a safe place on the Site one record copy of this Agreement (including all Amendments), the Owner’s Mandatory Requirements, Submittals, Final Submittals, Project Change Directives, Project Change Notices, the Contractor’s Proposal Documents, the Concept Drawings, the daily records described in Section 2.7(d) and quality assurance documentation, in good order and annotated to show all changes made during the performance of the Work. The Contractor will make all these documents available to OPG at any time for reference at the Site. On Substantial Completion, the Contractor will deliver those documents requested by OPG to OPG at the time and place designated by OPG.

(b) **Access to Areas.** If the Contractor requires access to any area outside of the Site, the Contractor will obtain, at its cost, such access for such purposes as the Contractor requires.

(c) **Designated Areas.** The Contractor will ensure that:

1. all Goods, construction equipment, tools, fuel and temporary structures and facilities, including for offices, lunchrooms, canteens, sanitation, showers, change rooms, accommodations, shops, warehouses and garbage disposal, whether in use or in storage; and

2. the operations of the Contractor and all Subcontractors,

will be restricted only to those areas designated “as available” on the Concept Drawings in Appendix 1.1(h) and any other areas outside of the Site permitted by Applicable Laws and will comply with the requirements set out in the Summary
of Work and the Owner’s Mandatory Requirements. The Contractor will ensure that all such temporary structures and facilities will be of metal construction and will be removed from OPG’s property when any such structure or facility is no longer needed, and in any event, within 60 days after the Final Completion Date. If the Contractor does not so remove any such structure or facility, OPG may remove such structure or facility at the Contractor’s cost. The Contractor will conduct all activities in the areas designated in accordance with this Agreement.

(d) **Surrounding Community and Environment.** The Contractor recognizes that the Site is located in an urban/tourist area and recognizes the potential intrusiveness of construction on the activities of the local residents and that the Tunnel Facility Project is subject to the constraints set out in the Summary of Work. The Contractor will ensure that the Contractor’s Personnel and each of the Subcontractors are aware of these conditions and the corresponding restrictions placed on them (e.g. noise limitations, transportation routes, respect for the local population and tourists, dust concerns) and that cooperation with local authorities and the public is essential. The Contractor will perform the Work in accordance with the Community Impact Agreement and conduct or attend meetings, participate in local committees, respond to information requests and do such other things as may be beneficial in maintaining a co-operative relationship with the local community. The Contractor will promptly notify OPG’s Representative of any complaints it receives from the public. The Contractor will co-operate fully with OPG’s Representative in responding to all complaints.

(e) **Site Conditions.** The Contractor will keep all of the Contractor’s Personnel fully informed in a timely manner of all Site rules and conditions and any changes to such rules and conditions.

(f) **Contractor Responsibility for Damages.** The Contractor will have exclusive responsibility for any damage, injury or loss to any area on the Site or to OPG or any other occupant of the Site or to any adjacent area, respecting the performance of the Work. The Contractor will make good and pay all costs incurred by others in making good any such damage, injury or loss. If any claim, demand, action, suit or proceeding is made against OPG by any Person for any Losses arising in respect of the Work, the Contractor will promptly resolve the claim. The Contractor will indemnify and hold harmless each member of the OPG Group, from and against all Losses suffered or incurred by a member of the OPG Group and all claims, demands, actions, suits or proceedings for Losses made against any member of the OPG Group by any Person in connection with any damage, injury or loss to any area on the Site or to OPG or any other occupant of the Site or to any adjacent area, to the extent arising in respect of the Work, including in respect of any breach of any Applicable Laws.

(g) **Clean Site.** During the performance of the Work on the Site, the Contractor will keep the Site, and any roads, Site accesses, sidewalks and walkways used in the course of performing the Work, free from accumulations of snow, ice, water, rubbish, debris and other waste materials. The Contractor will implement a
housekeeping program to ensure that all rubbish and debris is kept to a minimum and cleared away daily and that all materials are stored in a safe manner. Promptly following Substantial Completion, the Contractor will remove all rubbish, debris and other waste or surplus Goods from and about the Site as well as all applicable construction equipment, tools, fuel, temporary structures and facilities, including for offices, lunchrooms, canteens, sanitation, showers, change rooms, accommodations, shops, warehouses and garbage disposal, and all other Goods not otherwise necessary to complete punch list items. Except as set out in Section 2.15(c), any materials remaining to complete punch list items will be removed by no later than the Final Completion Date. The Contractor will leave the Site clean and ready for occupancy by OPG once the Tunnel Facility Project is entirely finished. The Contractor will restore to original condition, as at the date of this Agreement, all property not designated for alteration by this Agreement. In addition, the Contractor will provide any other cleaning activities required by this Agreement.

(h) **Signage on Site.** The Contractor will not erect signage on the Site directed to the public without OPG’s prior written approval.

(i) **Load Limits.** The Contractor will not load the Project, the Site or any roads used in the course of providing the Work and will ensure that no part of the Project, Site or such roads will be loaded in any manner that will endanger the Project, Site or such roads. The Contractor will not subject any part of the Project or any property on, under, over or near the Site to unsafe stresses or pressures.

(j) **Natural and Historical Objects.** All fossils, coins, articles of value or antiquity and structures and other remains or things of geological or heritage interest discovered on the Site shall be the absolute property of OPG. The Contractor will take all reasonable precautions and any precautions required by OPG to prevent the Contractor’s Personnel or other Persons from removing or damaging any such article or thing and immediately on discovery and before removal acquaint OPG of such discovery and carry out at the expense of OPG, OPG orders as to the preservation and disposal of the same. OPG will provide direction to the Contractor in connection with the precautions required by OPG to prevent the Contractor’s Personnel or any other Person from removing or damaging any such article or thing and in connection with the preservation and disposal of such article or thing and to the extent such direction has the effect of materially increasing the cost of time of performing the Work, then such direction will be treated as a Project Change Directive issued by OPG under Section 5.1.

(k) **Lands.** In addition to the Contractor’s obligations in Section 2.15(b), if, in the performance of the Work, the Contractor makes use of any interest, right of way, easement, license or other use right for access (an “Interest”) in land which is not required to be provided by OPG pursuant to Section 3.1(i), then the Contractor shall be responsible for acquiring the necessary Interest in such land at the Contractor’s cost. For greater certainty, this Section 2.15(k) will apply if the as-
built tunnel alignment deviates from the Interest required to be provided by OPG pursuant to Section 3.1(i).

2.16 Intellectual Property

(a) **Grant of Intellectual Property Rights.** The Contractor grants to OPG all rights (including ownership of the physical property) in the Work, Tunnel Facility Project, Submittals, results of the Work, and all other documents of any kind, designs, drawings (including as built drawings), inventions, ideas, processes, discoveries, techniques, diagrams, illustrations, schedules, performance charts, brochures, specifications, plans, photographs and other recordings, reports, manuals (including operating and maintenance manuals), software (hard copies and machine readable formats), information, data, models, samples and other deliverables whether complete or incomplete, provided or required to be provided by the Contractor to OPG under this Agreement (collectively the “Property”). Without limiting the foregoing, this grant includes all intellectual property rights (including all trade secrets, confidential information, patents, patent applications, rights to file patents, trade-marks, trade-mark applications, rights to file trade-marks, copyrights, industrial and similar designs, rights to file for industrial and similar designs, and know-how) contained, embedded or disclosed in or otherwise existing in respect of, used in the production of, or required or desirable for the provision, use, reproduction, modification, maintenance, servicing, improvement or continued operation of the Property (collectively, the “Intellectual Property”). Effective on the date of each such grant, each such item will be deemed to be Confidential Information owned by OPG, despite Section 2.17(a)(2).

(b) **No Diminishing of Intellectual Property Rights.** The Contractor will not take any action that may compromise or diminish the grant to OPG of rights in the Property. The Contractor will perform any acts required to confirm or document OPG’s rights in the Property. These acts include obtaining, at the request of OPG and at the Contractor’s expense, assignments of rights from the Contractor’s Personnel, as applicable, any applicable Subcontractor’s employees and any applicable Subcontractor. These acts also include providing, at OPG’s expense, access to the Contractor’s Personnel, as applicable, and any applicable Subcontractor to assist OPG to protect fully its rights in the Intellectual Property.

(c) **Exception and Licence.** Notwithstanding any term in Section 2.16(a), the Contractor and each Subcontractor retains its rights in its part of the Intellectual Property, so long as the Contractor or the applicable Subcontractor can establish through written records that such Intellectual Property existed before the earlier of, the date of this Agreement or the date that the Contractor commenced the Work (the “Retained Intellectual Property”). In respect of all such Retained Intellectual Property that the Contractor or a Subcontractor owns or claims to own, the Contractor grants to OPG, or, in the case of a Subcontractor, the Contractor will provide to OPG, at the Contractor’s cost, a perpetual, irrevocable, royalty-free, non-exclusive, fully paid up, freely assignable licence to:
(1) use all such Retained Intellectual Property in respect of the operation and maintenance, construction, commissioning, refurbishment, replacement, alteration, relocation, decommissioning, dismantling or demolition of the Sir Adam Beck Generating Complex and related facilities (including the Tunnel Facility Project), in whole or in part, to which the Retained Intellectual Property applies;

(2) use all such Retained Intellectual Property in respect of any transaction relating to the financing, sale, lease or other transfer of rights to a successor in interest involving the Sir Adam Beck Generating Complex and related facilities (including the Tunnel Facility Project), in whole or in part, to which the Retained Intellectual Property applies;

(3) disclose any Retained Intellectual Property to any Person who requires such Retained Intellectual Property in respect of any of the actions referred to in Section 2.16(c)(1) or 2.16(c)(2);

(4) use, reproduce, copy, transmit, modify and create derivative works from any Retained Intellectual Property; and

(5) sublicence any or all rights granted to OPG under this Section 2.16(c) to an affiliate of OPG or to any Person who provides goods or services to OPG.

(d) Representation and Warranty. The Contractor represents and warrants to OPG as follows.

(1) No Suits. There is no claim, demand or suit respecting any part of the Property, the Intellectual Property or the Retained Intellectual Property.

(2) No Potential Claims. There is no potential claim, demand or suit respecting the Property, the Intellectual Property or the Retained Intellectual Property, in whole or in part, that could affect the performance, function or use of the Property, Intellectual Property or Retained Intellectual Property, in whole or in part, as intended by this Agreement.

(3) Ownership. Before transferring ownership in the Property (including the Intellectual Property) to OPG, the Contractor is the exclusive owner of, and has good and marketable title to, all the Property. Except in regard to the Retained Intellectual Property, there is no ownership interest, agreement option or other right, title, benefit, interest or privilege outstanding in favour of any Person for the purchase or licence from the Contractor of, or any Lien in favour of any other Person in, any of the Property.
(4) **Right to Grant Licence.** The Contractor has the right to grant the licence rights in the Retained Intellectual Property and will obtain such rights from Subcontractors as contemplated by this Agreement.

(e) **OPG’s Remedy for Breach.** The Contractor will indemnify and hold harmless each member of the OPG Group from and against all Losses suffered or incurred by a member of the OPG Group and all claims, demands, actions, suits or proceedings for Losses made against any member of the OPG Group by any Person arising in respect of any breach or infringement or alleged breach or infringement by any member of the OPG Group of any right of any third party in any of the Property, the Intellectual Property or the Retained Intellectual Property. If any such claim, demand, action, suit or proceeding arises, the Contractor will, at its own cost:

1. obtain the right for OPG to continue using the Property, the Intellectual Property and the Retained Intellectual Property in the manner intended by this Agreement;

2. make such modifications to the Property, the Intellectual Property and the Retained Intellectual Property so that it becomes non-infringing, without incurring any diminution in the performance, function or use of the Property, the Intellectual Property or the Retained Intellectual Property, as intended by this Agreement; or

3. replace the Property, the Intellectual Property and the Retained Intellectual Property to the extent necessary with non-infringing substitutes, so long as such substitutes do not result in a diminution in the performance, function or use of the Property, the Intellectual Property or the Retained Intellectual Property as intended by this Agreement.

2.17 **Confidential Information**

(a) **Definition of Confidential Information.** In preparation for, and in the course of, performing the Work, OPG and OPG’s Representative will disclose to the Contractor certain OPG information which is confidential, a trade secret or otherwise proprietary to OPG, including this Agreement and the fact that the Contractor is performing the Work (collectively, the “Confidential Information”). Confidential Information does not include, however, information that the Contractor is able to demonstrate to OPG’s satisfaction, acting reasonably:

1. was or becomes generally known to the public through no fault of the Contractor, a Subcontractor or their respective shareholders, directors, officers, partners, members, representatives, agents, advisors or any of the Contractor’s Personnel or any other Person for whom the Contractor or any Subcontractor is responsible at law; or
was specifically known by the Contractor before disclosure by OPG and was not subject to any confidentiality obligation.

(b) **Ownership and Treatment of Confidential Information.** All Confidential Information remains, at all times, the exclusive property of OPG. Except as expressly set out in this Section 2.17(b), the Contractor has no licence or other right to use or disclose any Confidential Information for any purpose whatsoever. The Contractor may use Confidential Information only in respect of the preparation for, and the performance of, the Work, including in negotiations with proposed Subcontractors. The Contractor will ensure that none of its or any Subcontractor’s current or former shareholders, directors, officers, partners, members, representatives, agents and advisors or any of the Contractor’s Personnel or any other Person for whom the Contractor or any Subcontractor is responsible at law will use any of the Confidential Information for any purposes other than those expressly set out in this Section 2.17(b).

(c) **Return of Confidential Information.** At any time, at OPG’s request, the Contractor will deliver promptly to OPG all, or an OPG-specified portion of, the Confidential Information, together with all copies, extracts or other reproductions in whole or in part of such Confidential Information. In addition, at any time, at OPG’s request, the Contractor will destroy, demonstrably, promptly and irrevocably:

1. all such copies, extracts or other reproductions of Confidential Information, or an OPG-specified portion of Confidential Information, which cannot, because of the device on which such Confidential Information is stored, be removed from the possession of the Contractor by delivery to OPG; and

2. all documents, designs, drawings, specifications, plans, reports, information and other deliverables or data whatsoever (regardless of the form, medium or device on or in which such Confidential Information is written, recorded, stored or reproduced) prepared in respect of the Work and which is based on any of the Confidential Information.

Following such delivery and destruction, the Contractor will promptly provide OPG with written confirmation of completion. In any event, the Contractor will complete all such actions within 10 Business Days of receipt of OPG’s initial request.

(d) **Remedies.** The Contractor acknowledges that OPG would not have an adequate remedy at law for money damages if the Contractor fails to fulfill any of its obligations under this Section 2.17. Accordingly, in addition to any other remedies under this Agreement, OPG will be entitled to any injunction, specific performance or other remedy in law or equity (without being required to post a bond or other security), in respect of any breach or threatened breach of this Section 2.17 and in which case, the Contractor consents to any such injunction,
specific performance or other remedy in law or equity. The Contractor will indemnify and hold harmless each member of the OPG Group, from and against all Losses suffered or incurred by a member of the OPG Group and all claims, demands, actions, suits or proceedings for Losses made against any member of the OPG Group by any Person, to the extent arising in respect of a breach or threatened breach of this Section 2.17.

2.18 Conflicts of Interest

The Contractor has provided to OPG the declaration set out in Appendix 2.18, stating that, except as disclosed, the Contractor and all members of its consortium are free of actual or potential conflicts of interest. The Contractor will disclose any change in circumstance that may cause the declaration set out in Appendix 2.18 to be incorrect, inaccurate or incomplete. If the Contractor or consortium member discloses a change in circumstance during the course of the Tunnel Facility Project, OPG may request that the Contractor deliver further particulars regarding the conflict and may ask the Contractor to propose and institute measures which in OPG’s opinion satisfactorily address the conflict.

2.19 Language and Units of Measure

(a) Use of English Language. The Contractor will ensure that all communication between OPG and the Contractor and between the Contractor and each of the Subcontractors respecting the Work will be in English, including all drawings, notes on drawings and Submittals.

(b) Units of Measurement. The Contractor will ensure that the International System of Units (SI) will be used for all purposes with respect to the Work, including the calibration of any Goods.

(c) Risk. Any and all risk associated with language or units of measure shall be borne by and be for the account of the Contractor, howsoever the event may be caused.

2.20 Work Safety - INCW Part Project

The provisions in this Section 2.20 shall apply to the portion of the Work required for the INCW Part Project and carried out in the INCW Part Project Area.

(a) Primary Goal. Safety of the Contractor’s Personnel, individuals at or near the INCW Part Project Area and the public is of paramount concern to OPG. In the performance of the relevant Work, the Contractor will not in any manner endanger the safety of, or unlawfully interfere with, Persons on or off the INCW Part Project Area, including the public.

(b) Constructor. OPG will be the “constructor” (as that term is defined in the Occupational Health and Safety Act (Ontario)) in respect of the Work required for the INCW Part Project and carried out in the INCW Part Project Area. As such, OPG will submit the required notice of project and registration form to the
applicable Governmental Authority. OPG will also have the authority necessary
to carry out the role of “constructor” effectively.

(c) **Compliance.** The Contractor will perform all the Work required for the INCW Part Project in accordance with:

1. all Applicable Laws and applicable collective agreements;
2. and to the extent not inconsistent with Sections 2.20(c)(1), the INCW Part Project Specific Site Safety Plan, as described in Section 2.20(d);
3. and to the extent not inconsistent with Sections 2.20(c)(1) and 2.20(c)(2), the Contractor’s safety program (a copy of which is attached as Appendix 2.4(c), as amended from time to time); and
4. and to the extent not inconsistent with Sections 2.20(c)(1), 2.20(c)(2) and 2.20(c)(3), the very best of practices respecting health and safety and in a manner that recognizes and minimizes the risks to workers, other individuals and property.

The Contractor will forward to OPG, for OPG’s review and prior approval, without delay, any changes to the INCW Project Specific Site Safety Plan made during the course of performing the Work required for the INCW Part Project. OPG will monitor the compliance of the Contractor and Subcontractors with these requirements, including through field inspections during the course of the performance of the Work required for the INCW Part Project. The Contractor will rectify any deficiencies immediately upon written or verbal direction from OPG’s Representative. OPG may also have any aspect of the INCW Project Specific Site Safety Plan reviewed by inspectors and other Persons designated by OPG. The Contractor will provide these inspectors and other Persons with prompt access to the INCW Part Project Area and all premises and documents required for such review. The Contractor will forward to OPG, without delay, any change to the Council Amendment to Draft #7 (CAD-7) rating of the Contractor or to any Subcontractor performing Work in the INCW Part Project Area.

(d) **INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan.** The Contractor will have performed a safety hazard analysis to identify all significant safety hazards in respect of the Work required in the INCW Part Project Area. Based on this analysis and the Preliminary INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan, the Contractor will prepare a detailed safety plan for the INCW Part Project (as amended from time to time, the “INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan”) which will document how the Contractor will address all significant safety hazards related to the INCW Part Project, including the methodology for safe work planning and will include provision for the regular and systematic review and
audit of the plan elements by the Contractor to determine whether the INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan requires modification to more appropriately and effectively address all safety hazards associated with the Work required in the INCW Part Project Area. The Contractor will provide for the communication of the INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan to all workers performing Work on the INCW Part Project Area and all Subcontractors. The Contractor will submit the INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan to OPG as a Submittal within 30 days after the Start Date for review and comment and such plan will be deemed to form part of this Agreement. The INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan will be implemented by the Contractor. OPG retains the right to require modification of the INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan, to its sole satisfaction, including in order to ensure that the plan meets OPG’s safety requirements. To the extent OPG requires modification of the plan, the Contractor will modify the plan within 5 days after receiving Notice to do so from OPG. The Contractor will also submit to OPG the results of its own regular review and audit of the INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan, including modifications thereto, within 10 days after each review and audit. OPG will monitor the compliance of the Contractor and Subcontractors with the INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan through field inspections during the course of the performance of the Work required in the INCW Part Project Area.

(e) **Effect of Review.** If OPG reviews, comments on, accepts, rejects or fails to review, comment on, accept or reject any aspect of the Contractor’s or a Subcontractor’s safety program or the INCW Part Project Specific Site Safety Plan (including at a meeting or as part of OPG’s inspections or reviews), or if the Contractor or a Subcontractor satisfies or fails to satisfy any comments or concerns of OPG, such action or failure to act will not in any way relieve the Contractor from any of its safety obligations under this Agreement.

(f) **Safety Representative.** The Contractor will provide a qualified and experienced health and safety representative that will be responsible for the INCW Part Project Area. The Contractor will make this representative responsible for training the Contractor’s Personnel in safety, prevention of accidents and the maintaining, reviewing and revising of safety precautions and programs.

(g) **Safety Precautions and Remedies.**

1. **Protection.** Subject to a written or verbal direction from OPG’s Representative to the Contractor, the Contractor will be responsible for initiating, maintaining, reviewing, revising and supervising all safety precautions and programs in respect of the Work required for the INCW Part Project. The Contractor will take all necessary precautions (including
ensuring that all of the Contractor’s Personnel are equipped with, and properly use, all safeguards and personal protective equipment necessary for the performance of the relevant Work) for the safety of, and will provide the necessary protection to prevent damage, injury or loss resulting from the performance of the Work required for the INCW Part Project to:

(A) each Person who is in the INCW Part Project Area or who may otherwise be affected by the performance of the Work required for the INCW Part Project, including the Contractor’s Personnel and members of the public;

(B) any of the Goods, whether in storage on or off the INCW Part Project Area;

(C) the Tunnel Facility Project; and

(D) any other property on, under, over or near the INCW Part Project Area, whether belonging to OPG or to any other Person, including buildings and other structures, facilities, fences, gates, pavements, roadways, sidewalks, walks, vegetation, utilities and underground facilities that are not designated for removal and disposal in the course of performing the relevant Work.

(2) **Work Protection.** The Contractor will carry out the Work required in the INCW Part Project Area under work protection ensuring that equipment being worked on is safely isolated and de-energised. OPG will provide isolation and de-energisation, provided that the Contractor is responsible for co-ordinating all work protection with OPG’s Representative. Where the Contractor is required to perform elements of the Work under OPG's Work Protection Code, the Contractor's personnel directly involved in execution of the Work must complete required mandatory training as outlined in OPG, Electricity Production, Work Protection Code Training Requirements NPG-LP-HS-007 (current version dated April 15, 2003). All individuals who will be required to work as a work group member under a Work Protection must complete Level 2 - Worker Training (up to 1 hour). All individuals who will be required to hold Work Protection, and their supervisors, must successfully complete Level 5 - Instructor Led - Holder of Record Training (3 days plus field assignments). Requalification training is required every 2 years. The Contractor acknowledges that it has reviewed OPG’s Work Protection Code.

(3) **Notification of Owners.** The Contractor will promptly deliver a Notice to OPG’s Representative as the Contractor becomes aware of, and indicating the identity of, each utility, owner of underground facilities and owner of property (excluding OPG and its subsidiaries) on, under, over or near the INCW Part Project Area that may be affected by the relevant Work and
how each such utility or owner may be affected. OPG will deliver a Notice to the Contractor confirming the identity of each such Person and the Contractor will, at OPG’s direction, deal with or cooperate with OPG in dealing with settling any issue with such Person, including the protection, removal, relocation or replacement of the property of any such Person.

(4) **Repair of Damage.** To the extent that any third party, such as a utility, owner of underground facilities or owner of property (excluding OPG and its subsidiaries) on, under, over or near the INCW Part Project Area suffers or incurs any Losses to any property caused by the Contractor or a Subcontractor, the Contractor will remedy such Losses in a timely manner and at the Contractor’s expense. The Contractor will indemnify and hold harmless each member of the OPG Group from and against all Losses suffered or incurred by a member of the OPG Group and all claims, demands, actions, suits or proceedings for Losses made against any member of the OPG Group by a third party in connection with Losses suffered or incurred to any property of such third party caused by the Contractor or a Subcontractor.

(h) **INCW Part Project Specific Site Security, Public Safety and Emergency Response.** The Contractor will have performed a security, public safety and emergency response analysis to identify all public safety hazards associated with the INCW Part Project Area and the relevant Work and to identify all potential means of unauthorized access to the INCW Part Project Area. Based on this analysis and the Preliminary INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan, the Contractor will prepare a detailed project specific site security, public safety and emergency response plan for the INCW Part Project. Such plan as amended from time to time will be included in the INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan and will document, among other things, how the Contractor will address all significant public safety hazards and prevent unauthorized access to the INCW Part Project Area, the matters described in Appendix 2.4(g)(3) (which shall apply to the INCW Part Project, *mutatis mutandis*) and will include provision for the regular and systematic review and field inspection of the plan elements to determine whether the INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan requires modification. The Contractor will provide for the communication of the INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan to all workers performing Work on the INCW Part Project Area and all Subcontractors. The Contractor will submit the INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan to OPG as a Submittal within 30 days after the Start Date for review and comment and such plan will be deemed to form part of this Agreement. The INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan will be implemented by the Contractor. OPG retains the right to require modification of the INCW Part Project Specific Site
Safety, Security, Public Safety and Emergency Response Plan, to its sole satisfaction. To the extent OPG requires modification of the plan, the Contractor will modify the plan within 5 days after receiving Notice to do so from OPG. The Contractor will also submit to OPG the results of its own regular review and audit of the INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan, including modifications thereto, within 10 days after each review and audit. OPG will monitor the compliance of the Contractor and Subcontractors with the INCW Part Project Specific Site Safety, Security, Public Safety and Emergency Response Plan through field inspections during the course of the performance of the Work required in the INCW Part Project Area.

(i) **Safety Reports.** During the performance of the Work in the INCW Part Project Area, the Contractor will provide OPG’s Representative with:

1. a verbal report immediately of all accidents, near misses or “High Maximum Reasonable Potential for Harm” incidents (which are defined to be incidents that result in, or could reasonably be expected to result in, death from either immediate or delayed effects or permanent total disability, that is, where an individual is disabled to the point where maintaining gainful employment is unlikely) which the Contractor is required to provide to OPG in accordance with OPG’s safety incident management standard, as amended from time to time (which the Contractor has reviewed), including any serious incident requiring off-site medical attention or near miss incidents which do or could have resulted in the death of, or serious injury to, a worker or other Person on or off the INCW Part Project Area or an incident which has resulted in the death of or serious injury to a worker or other Person on or off the INCW Part Project Area;

2. an immediate verbal report of all High Maximum Reasonable Potential for Harm incidents (as that term is defined in Section 2.20(i)(1)) and evidence that a senior executive of the Contractor has also made this report immediately to OPG’s Representative;

3. within 24 hours of an accident, construction occurrence or incident report, a copy of all accident, construction occurrence and incident reports which the Contractor, any Subcontractor, or OPG is required to submit in respect of the relevant Work under the *Occupational Health and Safety Act* (Ontario) or the *Workplace Safety and Insurance Act, 1997* (Ontario);

4. within 24 hours, Notice of any visits by the Ministry of Labour and copies of any reports, orders to comply, charges, stop work orders, and notices of compliance under the *Occupational Health and Safety Act* (Ontario) or other Applicable Laws;

5. if there is a joint health and safety committee, a copy of the minutes of each meeting of the joint health and safety committee; and
(6) A monthly report within 10 days of each month’s end with safety statistics for the Contractor and all Subcontractors performing Work at the INCW Part Project Area. The Contractor will include in this report, with a brief description of each incident and injury:

(A) The number of injuries resulting in a worker requiring medical aid;

(B) The number of near miss incidents which could have resulted in the death of, or serious injury to, a worker;

(C) The number of injuries resulting in a worker’s absence from one or more complete shifts;

(D) The time each worker takes off from work for each injury;

(E) The number of Ministry of Labour orders to comply; and

(F) The total number of person hours worked by the Contractor’s Personnel broken down between the Contractor and each Subcontractor.

(j) **Stop Work Orders.** Where an order to comply, stop work order or any similar order or notice respecting the relevant Work is issued by the Construction Health and Safety Branch of the Ontario Ministry of Labour or any other Governmental Authority or OPG, where in OPG’s opinion, the stoppage is necessary to protect the safety of Persons or property, such order or notice will not be grounds for any change to the Contract Schedule or any other claim for delay or compensation, except to the extent that an action of OPG or another member of the OPG Group has resulted in such order or notice. To the extent OPG or another member of the OPG Group was immediately and directly responsible for causing the underlying circumstances giving rise to such order or notice, this situation will be deemed to constitute an excusable delay for the purposes of Section 6.2(a). The Contractor will promptly deliver to OPG’s Representative a copy of any such order or notice. The Contractor will not recommence any Work that has been stopped or suspended without the prior written approval of OPG’s Representative.

(k) **Investigations.** The Contractor will, at the Contractor’s expense, participate in, co-operate with OPG in, at OPG’s request, co-operate with any Governmental Authority in, and, at OPG’s request, carry out, reporting and investigating safety violations caused by any act or failure to act of the Contractor or any Subcontractor. To the extent that the Contractor, any Subcontractor, the Contractor’s Personnel or any of the Contractor’s or any of a Subcontractor’s shareholders, directors, officers, partners, members, representatives, agents, advisors or any other Person for whom the Contractor or any Subcontractor is responsible at law is responsible for the circumstances giving rise to a safety violation, the Contractor will pay OPG for the applicable portion of the costs and expenses incurred by OPG in respect of steps taken by OPG to investigate, report and/or alleviate the safety situation.
(l) **Emergencies.** In emergencies affecting the safety or protection of individuals, the relevant Work or the INCW Part Project or property on, under, over or near the INCW Part Project Area, the Contractor, without the express consent of OPG, will take reasonable actions to prevent or minimize all threatened or actual damage, injury and loss. The Contractor will indemnify and hold harmless each member of the OPG Group from and against all Losses suffered or incurred by a member of the OPG Group and all claims, demands, suits or proceedings for Losses made against any member of the OPG Group by any Person, to the extent arising in respect of any emergency medical treatment provided by any member of the OPG Group to any of the Contractor’s Personnel or any invitee of the Contractor or any Subcontractor.

(m) **Requirement to Leave.** In the case of an emergency requiring the Contractor to leave the INCW Part Project Area at the direction of OPG, the Contractor will put all equipment in a safe state in accordance with the Occupational Health and Safety Act (Ontario) and leave the INCW Part Project Area in an orderly fashion pending further instructions from OPG’s Representative.

(n) **Hazard Communication Programs.** The Contractor will co-ordinate all exchanges of material safety data sheets and other hazard communication information related to the Work required in the INCW Part Project Area to be made available to, or exchanged between or among, Persons in the INCW Part Project Area.

(o) **Designated Substances and Other Hazardous Materials.**

(1) The Contractor is solely responsible for any “designated substances” (as defined under the *Occupational Health and Safety Act (Ontario)*) brought onto the INCW Part Project Area by it, and shall fully remove any remaining amounts prior to or upon completion of the Work required in the INCW Part Project Area. The Contractor shall also ensure that in no event will designated substances be incorporated into the permanent facilities.

(2) Any other potentially hazardous materials or substances to which OPG personnel may be exposed during operation and maintenance of the facility must be in conformance with OPG's HAZMAT approved material list.

(3) The Contractor acknowledges that prior to execution of this Agreement, OPG provided the Contractor with a list of designated substances present at the INCW Part Project Area (a copy of which is attached as Appendix 2.20(o)), as required pursuant to the *Occupational Health and Safety Act (Ontario)*. OPG is not aware of any other designated substances at the INCW Part Project Area.
(p) **Direction from OPG.** Notwithstanding anything contained in this Section 2.20, as “constructor” (as defined under the *Occupational Health and Safety Act* (Ontario)) in respect of the Work required for the INCW Part Project, OPG retains the right to direct the Work performed on the INCW Part Project Area, in its sole discretion.

(q) **Indemnity Relating to Safety.** To the extent that the Contractor is responsible for, caused or contributed to, in whole or in part, the circumstances giving rise to a violation, charge, fine, order, direction, stop work order or other consequence pursuant to legislation applicable to worker health and safety, including the *Occupational Health and Safety Act* (Ontario) or its Regulations, the Contractor will indemnify and hold harmless each member of the OPG Group from and against all Losses suffered or incurred by a member of the OPG Group and from and against all claims, demands, actions, suits or any other proceedings for Losses made against any member of the OPG Group in connection with such violation, charge, fine, order, direction, stop work order or consequence.

### SECTION 3. OPG’S OBLIGATIONS

#### 3.1 Take Actions Promptly

OPG will take each of the following actions in a responsible manner so as not to materially delay the Contractor:

- **(a)** designate in writing from time to time an individual to act as OPG’s project representative to monitor performance of the Work and administer this Agreement;

- **(b)** provide access to Site, subject to any restrictions respecting certain parts of the Site set out in the Summary of Work or otherwise set out in this Agreement;

- **(c)** provide information known to OPG relating to the presence on the Site of Hazardous Material in addition to those described in this Agreement, in such quantities or circumstances that there is a material danger to any Person performing the Work;

- **(d)** discharge its obligations under Section 2.8 with respect to Submittals;

- **(e)** obtain those Approvals listed in the Summary of Work as being the responsibility of OPG, provided that the Contractor fulfills its responsibilities with respect to such Approval;

- **(f)** obtain such other Approvals as Contractor may identify as being required to be obtained by OPG, provided that the Contractor prepares the required documentation, submits it to OPG and supports the obtaining of such Approvals;
(g) provide the Contractor with all reasonable information and the required
documentation the Contractor, acting reasonably, identifies as being necessary to
prepare applications for Approvals;

(h) support the Contractor as and when the Contractor requests to obtain Approvals;

(i) acquire sufficient interest in the lands upon which the Tunnel Facility Project is to
be completed, the rights of way, easements, licenses and other use rights for
access thereto indicated on the Concept Drawings as necessary for performance of
Work; and

(j) furnish to the Contractor, as required for performance of the Work, the following,
all of which the Contractor may use and rely upon in performing the Work under
this Agreement:

(1) Environmental Assessment and Environmental Assessment Approval;

(2) property, boundary, easement, right-of-way surveys, 1:2000 topographic
information from aerial photographs dated 1989 at 1-m intermediate
intervals and indexed every 5 m; and

(3) the first order control monuments which in OPG’s judgment are necessary
to enable the Contractor to proceed with the Work.

3.2 Designation of OPG’s Representative and Delegation to OPG’s Designated
Delegates

OPG will designate in writing an individual to act as OPG’s Representative. OPG may, from
time to time change this designation, or delegate duties, to OPG’s Designated Delegates by
delivering a Notice in the form of Appendix 1.1(qq) to this effect to the Contractor.
OPG’s Representative will specify the scope and the limits of authority of each of OPG’s
Designated Delegates. Any changes to or revocations of any delegations will also be specified
by OPG’s Representative in writing in a Notice delivered to the Contractor. All Notices
delivered to OPG’s Representative, or OPG’s Designated Delegates (provided that the notice
relates to a matter within OPG’s Designated Delegate’s scope of authority), by the Contractor
will be as binding on OPG as if given to OPG under Section 14.4. If OPG has provided the
Contractor with a Notice delegating duties to OPG’s Designated Delegate as described in this
Section 3.2, the Contractor shall communicate solely with OPG’s Designated Delegate to the
extent specified in the Notice. The Contractor may rely on any written instructions, directions or
approvals (excluding safety related matters) provided by OPG’s Representative or OPG’s
Designated Delegates (provided such instructions, directions or approvals are within OPG’s
Designated Delegate’s scope of authority). OPG will take all reasonable steps to ensure that
OPG’s Representative and OPG’s Designated Delegates are accessible to the Contractor during
the performance of the Work (including outside of normal working hours in cases of
emergencies) and are available to render any necessary decisions or instructions promptly to
avoid delays to the Contract Schedule.
3.3 No OPG Control Over the Work

Except as may be necessary to fulfill its role as “Constructor” with respect to the INCW Part Project, OPG will not supervise, direct, have control or authority over, or otherwise be responsible for:

(a) the Contractor’s means, methods, techniques, sequences or procedures respecting the Work; or

(b) the safety programs and precautions used in respect of the Work, subject to OPG’s rights and obligations under the Occupational Health and Safety Act (Ontario).

OPG will not be responsible for any failure of the Contractor to comply with any Applicable Laws, Approvals or this Agreement in performing the Work. The Contractor acknowledges exclusive control over and commercial responsibility for any and all means, methods, techniques, sequences or procedures employed or necessary to complete the Work, for the Contract Price and in accordance with the Contract Schedule.

3.4 Hazardous Conditions

(a) **Division of Responsibility.** OPG will be responsible for the costs of dealing with any Hazardous Materials to the extent such Hazardous Material presents a material danger to any Person performing the Work (a “Hazardous Condition”) encountered at the Site that was not generally or specifically identified in this Agreement to be part of the Work. To the extent OPG is responsible for such costs and such Hazardous Condition has the effect of materially increasing the cost or time of performing the Work, then such change will be treated as a Project Change Directive issued by OPG under Section 5.1. Notwithstanding the previous sentence, the Contractor will be responsible for any Hazardous Condition caused by or resulting or arising from the performance of the Work or brought on the Site by or on behalf of the Contractor and no adjustment will be made to the Contract Price or Contract Schedule in respect of such Hazardous Condition.

(b) **Actions on Discovery.** Immediately on the discovery of a Hazardous Condition on the Site, the Contractor will:

1. in accordance with prudent practices, act to contain the Hazardous Condition in order to minimize the impact of the Hazardous Condition;

2. stop all Work in the area that could reasonably be affected by the Hazardous Condition, subject to Section 2.4(j); and

3. verbally notify OPG of the discovery and confirm by Notice within 24 hours of the discovery.
(c) **Corrective Action Plan.** The Contractor will implement a corrective action plan (and engage a specialized Subcontractor) and obtain any required Approvals. Such corrective action plan will be in accordance with prudent practices and will minimize impact on the Contract Price and Contract Schedule.

3.5 **INTENTIONALLY DELETED**

3.6 **INTENTIONALLY DELETED**

3.7 **Team Building Program**

OPG seeks to encourage a voluntary team building program for the Project. This program will be a structured approach to improve communication between OPG and its representatives and the Contractor and its Subcontractors, and to facilitate problem solving, conflict avoidance, and issue resolution. The team building program objective is to maximize the effectiveness of each Project participant’s resources to efficiently and safely achieve a quality end product, on time and within budget without unresolved disputes.

Participation in the program is totally voluntary. Any cost associated with program implementation will be agreed to by both parties and will be shared equally with no change in Contract Price. To implement this initiative, it is anticipated that within 60 days after the Start Date, the Contractor’s site manager and OPG’s on-site representative will develop a plan to hold a team building workshop to be attended by key staff of both Parties. Follow-up workshops will be held periodically throughout the duration of the Agreement as agreed to by the Contractor and OPG.

**SECTION 4. SECURITY DOCUMENTS AND INSURANCE**

4.1 **Security Documents**

(a) [INTENTIONALLY DELETED]

(b) [INTENTIONALLY DELETED]

(c) **Failure of Surety.** If the maintenance bond is cancelled for any reason or the surety issuing such bond is declared bankrupt, becomes insolvent, ceases to carry on any active business in Ontario or otherwise ceases to meet the requirements of this Agreement, the Contractor will notify OPG immediately and, within 60 days thereafter, deliver to OPG a substitute maintenance bond that complies with Section 4.1(f); provided that if the Contractor does not deliver the substitute bond to OPG prior to the 30th day after the maintenance bond is cancelled for any reason or the surety issuing such bond is declared bankrupt, becomes insolvent, ceases to carry on any active business in Ontario or otherwise ceases to meet the requirements of this Agreement, OPG will not be required to make payment to the Contractor under this Agreement unless and until the substitute bond is so delivered to OPG.
(d) **Letter of Credit.** On the Start Date, the Contractor will provide one or more letter(s) of credit in a total amount that is not less than $70 million (the “Performance LC(s)”). The Performance LC(s) shall be available for OPG for drawing (i) in the event of default by the Contractor hereunder; (ii) to satisfy any obligations of the Contractor in respect of Sections 8.1 and 8.3; or (iii) to be applied in respect of any obligations of the Contractor for which OPG has a right to set off hereunder. The Performance LC(s) and any other letter of credit to be delivered to OPG under this Agreement shall be a letter of credit acceptable to OPG substantially similar to the form set out in Appendix 4.1(d). The bank issuing the letter of credit must be acceptable to OPG and be set out in Schedule I of the Bank Act (Canada). Acceptance of any bank proposed by the Contractor shall not be unreasonably withheld, provided that acceptance may be withheld of a bank which does not have a credit rating of A- or higher by Standard & Poor’s or A3 or higher by Moody’s. Notwithstanding any term in this Agreement, OPG is not obliged to make any payment to the Contractor under this Agreement until the Contractor has delivered to OPG the Performance LC(s) and any other required letter of credit under this Agreement in accordance with this Section 4.1(d). The Contractor will maintain any letter of credit in force, at its expense, until the Final Completion Date. On the Final Completion Date, OPG will provide the Contractor with written confirmation addressed to the Contractor and the bank who issued the Performance LC, that the Performance LC is terminated.

(e) **Parental Indemnity.** On the date of this Agreement, the Contractor will provide to OPG the parental indemnities in the form set out in Appendix 4.1(e).

(f) **Maintenance Bond.** Prior to delivery of the Notice described in the first sentence of Section 7.10, the Contractor will deliver to OPG an original, signed maintenance bond in connection with the Contractor’s obligations under Sections 7.4(a), 7.8(d), 9.7, 9.8, 9.9 and 9.10 of this Agreement, in the form set out in Appendix 4.1(f) (or in such other form acceptable to OPG) and in an amount that is 10% of the Contract Price. The surety must be acceptable to OPG and licensed to issue such bonds in Ontario. Acceptance of any surety proposed by the Contractor shall not be unreasonably withheld, provided that acceptance may be withheld of a surety with A.M. Best ratings of below A- or a Standard & Poor’s rating below BBB. The Contractor will maintain the maintenance bond described in this Section 4.1(f) in force, at its expense, until the expiry of the Warranty Period as per Section 9.8(a)(1) (as such period may be extended in accordance with Section 9.8(d)).

4.2 **Required Insurance**

The Contractor will procure and maintain in full force and effect with financially responsible insurance carriers (with A.M. Best ratings of at least A- or a Standard & Poor’s rating of at least BBB) of recognized standing acceptable to OPG, or with the appropriate Governmental Authorities, all coverages referred to in this Section 4.2. The Contractor will ensure that all such coverages cover all Subcontractors and that all insurance coverages applicable in Ontario will be
obtained from insurance carriers that are duly licensed in Ontario to issue insurance policies for the limits and coverages required under Sections 4.2(a) to 4.2(f).

(a) **Workers’ Compensation.** The Contractor will maintain or cause to be maintained workers’ compensation coverage as required by the *Workplace Safety and Insurance Act, 1997* (Ontario) or any other Applicable Laws respecting all of the Contractor’s Personnel.

(b) **Additional US Requirements (as required).** In respect of all of the Contractor’s Personnel whose domicile of hire is the United States, the Contractor will maintain or cause to be maintained workers’ compensation coverage in each applicable state while any such Person is engaged in performing the Work. The Contractor will also ensure that any such coverage includes employer’s liability with a minimum limit of US$1,000,000 and, to the extent applicable, a foreign coverage endorsement, *Merchant Marine Act* (United States), *Longshore and Harbor Workers’ Compensation Act* (United States) and *Federal Employers’ Liability Act* (United States) coverage.

(c) **Motor Vehicle Liability Insurance.** The Contractor will maintain or cause to be maintained motor vehicle liability insurance on licensed motor vehicles owned, rented or leased by the Contractor and Subcontractors and used in connection with the Work to be performed under this Agreement covering bodily injury and property damage liability to a combined inclusive limit of not less than $5,000,000 per occurrence and mandatory accident benefits, continuously from the date of this Agreement until the expiry of the Warranty Period.

(d) **Construction Equipment Insurance.** The Contractor will be permitted to self-insure for all construction equipment and tools owned, rented or leased by the Contractor or a Subcontractor and used in respect of performing the Work.

(e) **Errors & Omissions Insurance.** Engineering consultants shall, at all times, maintain in full force and effect professional liability insurance in an amount not less than $10,000,000 per occurrence and in the aggregate, covering the period from start of conceptual design through to the Final Completion Date and for a further discovery period of five years from the Final Completion Date. Such insurance shall be obtained on or prior to November 1, 2005.

(f) **Marine Watercraft Hull and Liability Insurance (as required).** The Contractor will maintain hull and machinery insurance covering the full replacement cost of all barges, scows and other watercraft owned, rented or leased by the Contractor or any Subcontractor, and used in respect of performing the Work.

The Contractor will also maintain marine liability or protection indemnity insurance covering any barges, scows or other watercraft owned, rented or leased by the Contractor or any Subcontractor, and used in respect of performing the Work. The Contractor will ensure that this coverage covers special operations,
pollution liability and voluntary removal of wreck for limits that are the greater of those afforded under a protection and indemnity club and not less than $25,000,000 per occurrence.

OPG will procure and maintain in full force and effect with financially responsible insurance carriers (with A.M. Best ratings of at least A- or a Standard & Poor’s rating of at least BBB) of recognized standing, all coverages referred to in Sections 4.2(g) to 4.2(i). OPG will ensure that the coverage referred to in: (1) Section 4.2(h) will be maintained in force continuously from the Start Date until 60 days after the Final Completion Date or such other later date as OPG may designate; (2) Section 4.2(g) will be maintained in force continuously from and after the date the Contractor requires such coverage to be obtained, but in no event earlier than November 1, 2005 until 60 days after the Final Completion Date or such other later date as OPG may designate; and (3) Section 4.2(i) during the time period contemplated in Section 4.2(i). OPG will ensure that all such coverages cover all Work performed by the Contractor during the Warranty Period. OPG will ensure that all such coverages cover all Subcontractors and that all insurance coverages applicable in Ontario will be obtained from insurance carriers that are duly licensed in Ontario to issue insurance policies for the limits and coverages required under Sections 4.2(g) to 4.2(i).

(g) **Builders’ All Risks Insurance.** OPG will maintain builders’ all risks insurance on a repair or replacement cost basis, including OPG, any applicable subsidiary of OPG, OPG’s Designated Delegate, the Contractor and the Subcontractors as named insureds, to an aggregate limit of the Contract Price with a sublimit on Underground Work (as defined in the builders’ all risk policy) of $80,000,000 and such other sublimits as are customary, covering physical loss or damage to the Work, the materials, operating equipment, and supplies for incorporation therein, expendable construction tools, the TBM (however, excluding coverage for the perils of mechanical and electrical breakdown) and all temporary structures used in the performance of the Work or for which OPG is responsible, including property while in transit or elsewhere (except property insured under Section 4.2(i) below) before and during erection and until completed and while awaiting tests and during tests and until the Final Completion Date. This insurance shall be subject to the LEG 2/96 (The London Engineering Group Model “Consequences” Defect Wording) defects exclusion or equivalent and will include a 24 month maintenance period unless similar coverage for the maintenance period is included under the wrap-up liability insurance described in Section 4.2(h) below in which case OPG may elect to maintain coverage during the maintenance period under either the Builder’s All Risks Insurance policy or the Wrap-Up Liability Insurance policy.

(h) **Wrap-Up Liability Insurance.** OPG will maintain wrap-up liability insurance in the joint names of OPG, any applicable subsidiary of OPG, OPG’s Designated Delegate, the Contractor and the Subcontractors. This coverage will include limits of no less than $25,000,000 inclusive per occurrence for bodily injury, death and damage to property. OPG will also ensure that this coverage specifically includes:

(1) **blanket contractual liability;**
(2) pollution liability coverage on at least a sudden and accidental basis;
(3) blasting, pile driving, caisson services, underground services;
(4) products and completed operations, including a term that such coverage will be maintained throughout the Warranty Period;
(5) cross liability;
(6) severability of interests;
(7) employer’s liability;
(8) non-owned automobile liability;
(9) broad form property damage; and
(10) hook liability, if applicable.

If the Wrap-Up Liability Insurance provides coverage for a 24-month maintenance period and such coverage is similar to the coverage provided for such maintenance period under the Builder’s All Risk Insurance described in Section 4.2(g) above, OPG may elect to maintain coverage during the maintenance period under either the Builder’s All Risk Insurance policy or the Wrap-Up Liability policy.

(i) Marine Cargo Insurance (as required). OPG will maintain marine cargo insurance for all Goods while in the course of marine transit. Marine Cargo insurance may also include, at OPG’s option, inland transit. The Contractor will be an additional insured under the marine cargo insurance. OPG will ensure that this coverage will be in force from the time that such insured property leaves the last factory or warehouse of the Contractor or a Subcontractor, for shipment, and terminates after discharge at the Site. This insurance will include delay in start-up coverage.

4.3 General Insurance Terms

(a) Certificates of Insurance. Within 10 days after the date the Contractor is required to obtain insurance described in Sections 4.2(a) and 4.2(f), the Contractor will deliver to OPG certificates of insurance completed by a duly authorized representative of each of the Contractor’s insurers certifying that at least the minimum coverages required under Sections 4.2(a) to 4.2(f) are in effect. OPG will review the certificates of insurance within 10 Business Days. The Contractor agrees that it will not, and will not allow any of its agents, representatives or any of the Subcontractors, to access or enter the Site (the foregoing shall not restrict the Contractor from conducting on-Site visits under the supervision of OPG) until such insurance certificates in respect of the coverage described in Sections 4.2(a) and 4.2(c) have been delivered to OPG, in a form acceptable to OPG, in
accordance with this Section 4.3(a) and until OPG has obtained the insurance coverage described in Section 4.3(h). The Contractor will ensure that each certificate will state that the coverages will not be cancelled, will not fail to be renewed and will not be materially changed by endorsement or through issuance of any other policy of insurance which restricts or reduces coverage, without 60 days advance written notice by courier given to OPG’s Representative, with a copy delivered by fax as follows:

Ontario Power Generation Inc.
Risk Management & Insurance - Treasury
700 University Avenue H18-H17
Toronto, Ontario, Canada M5G 1X6

Attention: Director, Risk Management & Insurance
Fax: 416-592-4775

To the extent that the Contractor is required to maintain any coverages under Sections 4.2(a) to 4.2(f) in force after final payment of the Contract Price, the Contractor will deliver to OPG, at the time that the Contractor submits its Final Application for Payment for the Contract Price, a certificate of insurance completed by a duly authorized representative of such Person’s insurer certifying that such insurance will remain in force for the period of time required under Section 4.2. Within 10 days after the Start Date, OPG will deliver to the Contractor a certificate of insurance completed by a duly authorized representative of OPG’s insurers certifying that at least the minimum coverages required under Section 4.2(h) are in effect.

(b) **Copies of Policies.** Within 30 days after the date the Contractor is required to obtain the insurance described in each of Section 4.2(a) to 4.2(f), the Contractor will provide OPG with a certified copy of any insurance policy referred to in each of Sections 4.2(a) to 4.2(f). Within 90 days after a request by Contractor, OPG will provide Contractor with a certified copy of any insurance policy referred to in Section 4.2(h) and, if then in effect, Sections 4.2(g) and 4.2(i).

(c) **No Waiver by OPG.** If OPG fails to demand any certificate referred to in Section 4.3(a) or otherwise fails to demand other evidence of full compliance with Sections 4.2 or 4.3 or fails to identify a defect from evidence provided, OPG has not waived, and OPG will not be deemed to have waived, any of the Contractor’s obligations. The Contractor’s obligation to purchase and maintain insurance under this Agreement will in no way limit or otherwise qualify the liabilities or obligations of the Contractor under this Agreement.

(d) **No Approval by OPG.** If OPG receives, reviews and accepts any certificate or other evidence under this Section 4.3, OPG has not approved or agreed, and OPG will not be deemed to have approved or agreed, that the Contractor has satisfied any of its obligations under Sections 4.2 or 4.3.
(e) **OPG May Purchase Insurance.** If the Contractor fails to maintain any insurance required under Sections 4.2(a) to 4.2(f) or any such insurance is inadequate in its scope, OPG may purchase any such insurance, at the Contractor’s sole expense, or OPG may terminate this Agreement immediately due to default by the Contractor in accordance with Section 10.1(m). In the event that OPG must purchase insurance under this subclause, OPG may set off the costs thereof against any monies then or thereafter due, owing or payable to the Contractor and may set off and retain, in addition, and in consideration for its services in procuring such insurance, an amount equal to the cost thereof, in addition to the cost of such insurance.

(f) **Deductibles.** The Contractor will pay the amount of all deductibles under this Agreement and, subject to the immediately following sentence, the Contractor may not charge back any such amount to OPG. In the event that the deductible in respect of a claim under:

1. the Builder’s All Risks Insurance described in Section 4.2(g) exceeds the amounts set out below for the coverage referred to:

<table>
<thead>
<tr>
<th>Coverage</th>
<th>Deductible</th>
</tr>
</thead>
<tbody>
<tr>
<td>TBM (as defined in the builders’ all risk insurance policy)</td>
<td>greater of $500,000 or 10% of the value of the claim, per claim.</td>
</tr>
<tr>
<td>Underground Works (“as defined in the builders’ all risk insurance policy”)</td>
<td>$2,000,000 per claim</td>
</tr>
<tr>
<td>All Other (“as defined in the builders’ all risk insurance policy”)</td>
<td>$250,000 per claim</td>
</tr>
</tbody>
</table>

   (as applicable, the “BAR Cap”);

2. the Wrap-Up Liability Insurance described in Section 4.2(h) exceeds $100,000 per claim (the “WUL Cap”); and

3. the Marine Cargo Insurance described in Section 4.2(i) exceeds $50,000 per claim (the “MC Cap”),

the Contractor will pay the amount of the deductible for such claim but may charge back to OPG any amount actually paid by the Contractor as a deductible for such claim under such Builder’s All Risk Insurance, Wrap-Up Liability Insurance, or Marine Cargo Insurance in excess of the BAR Cap, the WUL Cap or the MC Cap, respectively.

(g) **Insurance Not Contributory.** With the exception of the insurance referred to in Section 4.2(c), the Contractor will ensure that all other insurance referred to in
Sections 4.2(a) to 4.2(f) will specify that such insurance is primary coverage and not contributory with, or in excess of, any insurance that may be maintained by OPG.

(h) **Subrogation.** The Contractor will ensure that each insurer which provides insurance under Sections 4.2(b), 4.2(d) and 4.2(f) will provide a waiver of subrogation to OPG, any applicable subsidiary of OPG, OPG’s Designated Delegates, the Contractor and all the Subcontractors.

(i) **OPG as Additional Insured.** The Contractor will ensure that each insurer that provides insurance under Sections 4.2(c), 4.2(e) and 4.2(f) will include OPG, any applicable subsidiary of OPG, OPG’s Representative and OPG’s Designated Delegates as an additional insured.

(j) **No Invalidation by OPG.** The Contractor will ensure that no insurance referred to in Sections 4.2(a) to 4.2(f) will be invalidated or vitiated by any action or failure to act by OPG, any applicable subsidiary of OPG, OPG’s Representative or OPG’s Designated Delegates, or by any breach by the Contractor or any other Person of any declarations, warranties or other terms in such policies.

(k) **Notice of Claim.** In connection with the insurance described in Sections 4.2(a) through 4.2(i), the Contractor will assert all of its claims directly to the insurer which provides such insurance and will be responsible to process and settle all such claims directly with the insurer; OPG will not be responsible to assert any of the Contractor’s claims against the insurer nor will OPG be responsible for the processing or settlement of any such claim. The Contractor will deliver a Notice to OPG’s Representative at least three Business Days prior to asserting any claim under any insurance referred to in Sections 4.2(g), 4.2(h) or 4.2(i). The Contractor will include in the Notice the date of the events giving rise to the claim, a summary of the circumstances respecting the claim and the amount of the claim. The Contractor will provide OPG any additional information respecting the claim that OPG’s Representative may request. With respect to any assertion by the Contractor of a claim under any insurance referred to in Sections 4.2(g), 4.2(h) or 4.2(i), OPG will promptly review the claim to verify that the claim is in accordance with the requirements of the insurance policy. The Contractor will not be permitted to assert any claim under any insurance referred to in Sections 4.2(g), 4.2(h) or 4.2(i), until OPG has completed its review and verification of such claim.

### 4.4 Construction Equipment

In respect of each member of the OPG Group, the Contractor waives all Losses whatsoever arising in respect of loss of, loss of use of, or damage to any construction equipment, tools, fuel and temporary structures and facilities, including for offices, lunchrooms, canteens, sanitation, showers, change rooms, accommodations, shops, warehouses and garbage disposal.
SECTION 5. CHANGES IN WORK

5.1 Changes Requested by OPG

(a) **Issue Project Change Directive.** OPG may, without invalidating this Agreement, direct the Contractor to make changes in the Work by issuing a Project Change Directive. If OPG issues a Project Change Directive, the Parties will execute an Amendment made in accordance with this Section 5 covering the applicable changes to the Work and the changes, if any, to the Contract Price or Contract Schedule. OPG may include in any Project Change Directive, OPG’s expectations as to the changes, if any, that the changes in the Work will cause to the Contract Price and Contract Schedule. OPG may amend the Owner’s Mandatory Requirements by issuing a Project Change Directive.

(b) **Review of Project Change Directive.** At OPG’s request, the Contractor will review the Project Change Directive before making the changes and advise OPG as to the Contractor’s views as to:

1. any impact of the change on the Tunnel Facility Project that the Contractor is aware of;
2. any proposed change to the Contract Price, calculated in accordance with Section 7.7; and
3. any proposed changes to the Contract Schedule and/or material changes to the detailed contract schedule described in Section 2.7(a)(3), that the Contractor estimates will occur as a result of such changes.

The Contractor acknowledges that a change in the Contract Schedule will not necessarily result in a change in the Contract Price. The Contractor will cooperate with OPG and will use all reasonable efforts to carry out each Project Change Directive in such a manner so as to avoid or minimize any additions to the Contract Price and changes to the Contract Schedule.

(c) **Obligation to Implement Project Change Directive.** OPG may require, in any Project Change Directive, that the Contractor proceed with the Project Change Directive before the Parties have agreed on the terms of an Amendment. Upon receipt of any such Project Change Directive, the Contractor will comply with the applicable Project Change Directive and any Dispute will be resolved in accordance with Section 5.7. Section 2.7(e) expressly applies to any changes set out in a Project Change Directive.

5.2 Changes Requested by the Contractor

The Contractor will not make any change in the Work except in accordance with this Section 5. The Contractor will ensure that no changes are made in the Work without the prior written consent of OPG’s Representative in a Project Change Directive. If the Contractor desires to make any changes in the Work, in whole or in part, the Contractor must first advise OPG in a
Project Change Notice as to the matters referred to in Section 5.1(b) and obtain the prior written consent of OPG’s Representative in a Project Change Directive. Nothing in this Agreement obliges OPG to agree to any change proposed by the Contractor. OPG may in its sole and absolute discretion refuse to agree to any change affecting quality of the Work (as determined by OPG), the Contract Schedule or the Contract Price. OPG will, however, act reasonably in approving any other change. Any written consent of OPG’s Representative in a Project Change Directive to any such proposed change requested by the Contractor will constitute a Project Change Directive issued by OPG in accordance with Section 5.1. If the change requested by the Contractor results in cost savings and the Parties agree on such net amount of savings (calculated based on Section 7.7(b)), the Parties will execute an Amendment made in accordance with this Section 5 reducing the Contract Price by 50% of such net amount of savings and making all other necessary changes to this Agreement including changes to the Contract Schedule.

5.3 Changes in Applicable Laws

If, after the date of this Agreement, there is any:

(a) change in Applicable Laws (except those that relate to Taxes) or any applicable standards, specifications, manuals or codes of any technical organization or Governmental Authority; or

(b) new Canadian federal or provincial sales, use or excise taxes or any changes in the rates of such taxes,

which directly and materially impacts the Work or Contract Schedule that is neither known nor foreseeable on the date of this Agreement and that has the effect of materially increasing or decreasing the cost or time of performing the Work, then such change will be treated as a Project Change Directive issued by OPG under Section 5.1. The Contractor will promptly provide OPG’s Representative with a Notice in the form of Appendix 5.3 detailing the impact the change described in Section 5.3(a) or 5.3(b) has on the Work, Contract Price and Contract Schedule. OPG’s Representative will discuss the impact and provide a prompt direction to the Contractor resolving the issue by way of a Project Change Directive. Any dispute relating to changes to the Contract Schedule or Contract Price will be resolved in accordance with Section 5.7. Any other disputes relating to the impact of the change described in Section 5.3(a) or 5.3(b) will be resolved in accordance with Section 11.

5.4 Geotechnical Baseline Report

The GBR shall serve as the only basis for determining changes in or differing geotechnical subsurface conditions. The GBR has been developed jointly by OPG and the Contractor and, as such, describes anticipated behaviours and conditions that are dependent on the Contractor’s selected designs, means, methods, sequences, timing and level of workmanship anticipated or implied at the date of this Agreement. Notwithstanding OPG’s participation in the development of the GBR, OPG has no liability with respect to such designs, means, methods, sequences, timing and level of workmanship, and such participation will not have the effect of transferring any obligation under this Agreement from the Contractor to OPG or otherwise have the effect of amending this Agreement. The Parties acknowledge that such means, methods, sequences,
timing and level of workmanship are the sole responsibility of the Contractor, and the Contractor
is free to make changes at any time. To the degree that any difference in the behaviour of the
gеotechnical subsurface conditions is attributable to a change or deficiency in the designs,
means, methods, sequences, timing and level of workmanship, then the Contractor will not be
entitled to make any claim for the impacts resulting therefrom.

5.5 Differing Subsurface Conditions

(a) Upon identification of геotechnical subsurface conditions which differ materially
from those indicated in the GBR, the Contractor will promptly and in any event
no more that 5 days after identification and before the conditions are disturbed,
give Notice to OPG of such difference (“Initial Notice”). Such Notice will be
followed up within 5 days with a Project Change Notice which will address the
matters referred to in Section 5.1(b).

(b) OPG will investigate the subsurface conditions promptly after receiving the Initial
Notice. If OPG determines that:

(1) the conditions are found to differ materially from the GBR;

(2) the material difference in the conditions is not attributable to a change or
deficiency in the Contractor’s designs, means, methods, sequences, timing
and/or level of workmanship;

(3) the conditions directly and materially impact performance of the Work;
and

(4) such impact has the effect of materially increasing or decreasing the cost
or time of performing the Work,

then OPG may issue a Project Change Directive indicating the extent, if any, of a
change in the Contract Price or the Contract Schedule that OPG attributes to such
differing conditions, calculated in accordance with Section 7.7. If OPG declines
to issue a Project Change Directive, or the Contractor disagrees with the proposed
changes to the Contract Schedule or Contract Price, the resulting Dispute will be
resolved in accordance with Section 5.7.

(c) Notwithstanding Sections 5.5(a) and 5.5(b) and in lieu of the procedure described
in Sections 5.5(a) and 5.5(b), the following procedure shall apply in full
satisfaction of any change to the Contract Price and Contract Schedule relating to
rock support resulting from differing subsurface conditions (the “Rock Support
Adjustment”):

(1) on a continuous basis during the performance of the Work, the Contractor
will record the rock conditions (as defined in the GBR) encountered in the
performance of the Work and measure the tunnel lengths thereof and OPG
will review and verify such determinations. If the parties cannot agree, the
positions of both parties shall be recorded. The resolution of any
disagreements will be held in abeyance until the step described in section (4) below has been completed, unless the parties mutually agree that the issue is sufficiently material that the issue should be referred to dispute resolution in which event the matter be resolved in accordance with Section 11;

(2) within two months after the TBM Completion Date, the parties shall determine the total length of the TBM-bored tunnel;

(3) following the determination in (2) above, OPG shall complete the table in Appendix 1.1(j) entitled “Rock Support Table” using the data recorded in item (1) (and in the event of disagreement, using the data assuming OPG’s position); and

(4) OPG shall promptly thereafter issue a one-time Project Change Directive setting out the net change to the Contract Price and Contract Schedule determined by completing the Rock Support Table as set out in (3) above.

If OPG declines to issue a Project Change Directive in connection with the Rock Support Adjustment or the Contractor disagrees with the proposed changes to the Contract Price and Contract Schedule (including, for greater certainty, because of a disagreement on the rock conditions or the tunnel lengths thereof), the resulting dispute will be determined in accordance with Section 5.7.

(d) No request for relief for differing subsurface conditions will be allowed and no change to the Contract Price or Contract Schedule will be made in respect of replacing, repairing, remedying or otherwise fixing rock support that was installed in the performance of the Work but is later determined to be inadequate or in need of replacement, repairing, remedying, or fixing.

(e) No request by the Contractor for relief for differing subsurface conditions will be allowed in respect of Work under the St. Davids Gorge to the extent that the width of the gorge is within the width defined in the GBR.

(f) The Contractor acknowledges that the existence of geotechnical subsurface conditions which differ from those indicated in the GBR shall in no way:

(1) affect the Contractor’s obligation to pay liquidated damages pursuant to Section 8.3 if the Guaranteed Flow Amount is not achieved; nor

(2) entitle the Contractor to claim that it would have received the bonus payment described in Section 8.4 had the geotechnical subsurface conditions not differed from those indicated in the GBR.

(g) Except as set out in Section 5.5(c) above, no request by the Contractor for relief for differing subsurface conditions will be allowed unless the Contractor has given the Initial Notice and the Project Change Notice required in Section 5.5(a).
5.6 Execution of Amendments

OPG will not be deemed to have agreed to, or be required to pay for, any changes to the Work, Contract Price or the Contract Schedule, until the Parties have executed an Amendment evidencing the Project Change Directive. Once the changes resulting from a Project Change Directive have been agreed to or resolved in accordance with Section 5.7, the Parties will execute an Amendment covering the applicable changes to the Work, Contract Price and Contract Schedule.

5.7 Resolution of Claims

(a) Filing Notice of Claim. If the Parties are unable to agree as to the extent, if any, of a change in the Contract Price or the Contract Schedule that should be made as a result of changes in the Work under Sections 5.1, 5.2, 5.3 or 5.5, either Party may deliver a Notice in the form attached as Appendix 5.7(a) of its intent to the other Party to resolve the Dispute under this Section 5.7. The Party delivering any such Notice will deliver it promptly, and in any event not later than five Business Days, after the circumstances giving rise to the Dispute first arose. If a Party fails to deliver such Notice in a timely manner, the other Party may, in its sole and absolute discretion, dismiss the Dispute. In such a case it will be deemed that there is no Dispute and the position of the Party dismissing the Dispute will prevail.

(b) Claim Documentation. The Party that delivers a Notice under Section 5.7(a) will submit to the other Party all reasonable documentary evidence and a concise statement of the rationale of the Party’s position within 5 Business Days after delivery of such Notice.

(c) Decision. The Party receiving a Notice under Section 5.7(a) will review the documents and rationale received under Section 5.7(b) and will render a decision, including a concise statement setting out the reasons for its decision, no more than five Business Days after the receipt of the documents and rationale received under Section 5.7(b). This decision will be final and binding on the Parties unless the Party giving Notice under Section 5.7(a) gives to the other Party, within 5 Business Days of receiving the decision, a Notice of its intention to have the decision resolved under the dispute resolution process under Section 11 and such process is commenced within 5 Business Days after giving the notice of intent.

SECTION 6. CHANGES TO CONTRACT SCHEDULE AND DELAYS

6.1 Changes to Contract Schedule

The Contract Schedule may only be changed by an Amendment made in accordance with Section 5. No other purported change to the Contract Schedule will be valid. Except as set out in this Agreement, nothing in this Agreement obliges OPG to agree to any change to the Contract Schedule.
6.2 Time Extensions

(a) **Excusable Delays.** Neither Party will be responsible for any delay in fulfilling any obligation under this Agreement to the extent the delay has a material impact on the ability of the Contractor to meet the Contract Schedule and is caused by: 

1. OPG or another member of the OPG Group being responsible for causing the underlying circumstances giving rise to a stop work order or similar notice under Section 2.4(i); or

2. tidal wave, lightning, earthquake, cyclone, legal strike or lockout on the Site, war, riot or act of public enemies, including terrorists.

(b) **Exceptions to Excusable Delays.** Section 6.2(a) does not apply to the extent a delay is caused by the fault or negligence of the Party seeking relief because of the delay. Section 6.2(a) does not apply if the Party seeking relief on account of the delay fails, within three Business Days after the commencement of any such delay, to give a Notice in the form attached as Appendix 6.2(b) to the other Party describing the event under Section 6.2(a) giving rise to the delay and the anticipated period of the delay. Failure by the Contractor to give such Notice within such three Business Day period is sufficient reason for denial by OPG of any extension of time.

(c) **Delays caused by OPG.** OPG will be responsible for any delay caused as a result of OPG:

1. failing to obtain the Approvals required pursuant to Sections 3.1(e) and 3.1(f);

2. failing to acquire sufficient interest in the lands required pursuant to Section 3.1(i);

3. failing to furnish to the Contractor the items and information required pursuant to Sections 3.1(c) and 3.1(j);

4. failing to discharge its obligations pursuant to Section 3.1(d);

5. requesting the Contractor to uncover a part of the Project where no Defective part of the Work was found as described in Section 9.4(c); and

6. not having paid the amounts required under Section 7.3(b) within 30 days of the date OPG is required to make payment under Section 7.3(b) and the Contractor has suspended the performance of the Work in accordance with Section 2.7(e).

If the delay resulting from events referred to in this Section 6.2(c) has resulted or will result in the Contractor being unable to meet the Contract Schedule, the Parties will execute an Amendment made in accordance with Section 5 covering
the applicable changes to the Contract Schedule. The Contractor will act prudently in all respects to mitigate the impact of the delay on the Contract Schedule.

(d) **Subcontractors and Suppliers.** Delays attributable to or as a result of delays caused by or within the control of Subcontractors or suppliers shall be deemed to be delays within the control of the Contractor and the Contractor shall not be granted any extension of time.

(e) **Compensation.** Subject to Section 6.2(b), the Contractor will be entitled to compensation by way of an increase in the Contract Price, calculated in accordance with Section 7.7, for material delays impacting the Work resulting from events referred to in Sections 6.2(a)(1) and 6.2(c) where the delay has the effect of materially increasing the cost of performing the Work. The Contract Price may not be increased, however, by an amount that is more than is reasonably attributable to the event that caused the material delay. The Contractor will not be entitled to any additional compensation in respect of any delay referred to in Section 6.2(a)(2).

(f) **Actions During Delay.** During any period of delay resulting from events referred to in Section 6.2(a), the Party that delivered the Notice under Section 6.2(b) will:

(1) act prudently in all respects to mitigate the impact of the delay on the Contract Schedule; and

(2) keep the other Party informed in a timely manner of the status of the event under Section 6.2(a) giving rise to the delay and of the actions being taken to mitigate the impact of such delay.

(g) **Steps After Delay Ends.** Within three Business Days after cessation of the period of delay resulting from events referred to in Section 6.2(a), the Party that delivered the Notice under Section 6.2(b) will deliver an updated Notice in the form attached as Appendix 6.2(b) to the other Party specifying the alleged duration of the excused delay and its impact, if any, on the Contract Schedule. The Party receiving such Notice will review such Notice and provide for an equitable change, if any, to the Contract Schedule in an Amendment made in accordance with Section 5. The Contract Price may also be changed to the extent permitted by Section 6.2(e). The dates in the Contract Schedule may not be extended by more than the delay reasonably attributable to the event causing the delay. If the Parties are unable to agree to a change in the Contract Schedule, either Party may file a claim under Section 5.7(a).

**SECTION 7. PAYMENT OF CONTRACT PRICE AND CHANGES**

7.1 **Schedule of Values**

Within 60 days after the Start Date, the Contractor will provide to OPG for its approval, acting reasonably, a schedule of values breaking down the Contract Price into manageable elements for
measurement and payment, reflecting the subtotals set out in Appendix 1.1(j) under the heading “Breakdown of Contract Price”. Once approved by OPG, such schedule will be deemed the “Schedule of Values” and will become a Final Submittal in accordance with Section 2.8(g).

7.2 Application for Payment

OPG will make progress payments to the Contractor for each item in the Schedule of Values in accordance with the measurement for payment schedule set out in Appendix 7.2 and in accordance with this Section 7. The Contractor will submit only one draft Application for Payment to OPG’s Representative monthly for acceptance in respect of Work performed to the end of the previous month. After receiving OPG’s Representative’s acceptance, the Contractor will electronically deliver to OPG (at apmailroom@opg.com) a complete Application for Payment. The Contractor will so deliver each Application for Payment in .pdf or .tif format. As part of each Application for Payment, the Contractor will submit to OPG:

(a) an invoice containing:

(1) the total amount owing by OPG (showing separately all amounts of Ontario Retail Sales Tax included in the Contract Price and all amounts due as goods and services tax levied under the *Excise Tax Act* (Canada) and expressly stating any amounts invoiced in a currency other than Canadian dollars);

(2) the OPG purchase order number;

(3) the Contractor’s full name and address;

(4) the name of a contact individual at the Contractor, with a telephone number;

(5) electronic transfer instructions;

(6) the Contractor’s invoice number (which must be unique for each invoice);

(7) the invoice date (which must be the date the invoice is delivered);

(8) the Contractor’s registration number for the purposes of Part IX of the *Excise Tax Act* (Canada);

(b) a statutory declaration in the form set out in Appendix 1.1(d) signed by a director or officer of the Contractor declaring that:

(1) all payments due to Subcontractors, all wages and benefit payments due to any of the Contractor’s Personnel, and all contributions, premiums, allowances and remittances due to any Governmental Authority, pension fund, benefit plan, or union fund in accordance with a collective agreement or Applicable Laws, have been paid on or before the date of the
Application for Payment in a timely manner, subject to any withholdings or holdbacks required by Applicable Laws; and

(2) title to the applicable part of the Tunnel Facility Project will pass to OPG in accordance with Section 7.4 no later than the date of OPG’s payment; and

(3) there are no known unnotified claims for extra time or extra compensation of any nature or kind whatsoever as of the date of the statutory declaration.

(c) a certificate in the form set out in Appendix 1.1(d) signed by an officer of the Contractor certifying,

(1) that the coverages that the Contractor is obliged to maintain under Section 4.2 remain in full force,

(2) that the Contractor has paid in a timely manner all amounts payable under the Workplace Safety and Insurance Act, 1997 (Ontario),

(3) that the Contractor remains in compliance with all its other obligations under the Workplace Safety and Insurance Act, 1997 (Ontario), and

(4) that the Contractor has provided OPG with the Workplace Safety and Insurance Board registration number for each member of the Contractor’s Personnel performing Work at the Site for the period covered by the certificate;

(d) a certificate in the form set out in Appendix 1.1(d) signed by an officer of the Contractor respecting outstanding claims; and

(e) a certificate of compliance from the Workplace Safety and Insurance Board as to the Contractor’s status and that of all Subcontractors that will be performing Work at the Site.

7.3 Progress Payments

(a) OPG Reviews Each Application for Payment. OPG will, within 10 Business Days after receipt of each Application for Payment relating to the Schedule of Values, either provide a written Notice in the form of document attached as Appendix 7.3(a) approving the Application for Payment or return the Application for Payment to the Contractor indicating in writing OPG’s reasons for rejection.

(b) Payment Terms. Only Applications for Payment that are approved by OPG for payment before the 25th day of the month will be processed for payment on the 25th day of the following month. Subject to Sections 7.3(c), 7.3(f) and 7.5(e) and OPG’s right to set off under this Agreement and pursuant to Applicable Laws, OPG will pay the Contractor the amount of the approved Application for Payment on the 25th day of the following month. Payments due but unpaid shall bear
interest at the rate equivalent to the prevailing Bank of Canada Prime Lending Rate plus 2%. Interest shall commence accruing on the 31st day after payment is due.

(c) **Construction Lien Act (Ontario) Holdbacks.** Notwithstanding any term in this Agreement, OPG will retain 10% of the amount of each approved Application for Payment, or such greater amount as may be required, to satisfy OPG’s obligation under the *Construction Lien Act* (Ontario). OPG will only pay to the Contractor the total accumulated 10% holdback when final payment is made under Section 7.12, to the extent that such amount has not otherwise been paid to another Person under this Agreement. Under no circumstances, however, will OPG be obliged to release any such holdback, in whole or in part, that OPG retains in accordance with the *Construction Lien Act* (Ontario) on any date that is earlier than permitted under that statute.

(d) [INTENTIONALLY DELETED]

(e) **No Deemed Acceptance.** No payment made by OPG under this Agreement and no use or occupancy of the Project, in whole or in part, by OPG will constitute acceptance of any part of the Work that is not in accordance with this Agreement.

(f) **Refusal of Payment.** Notwithstanding any term in this Agreement, OPG may refuse to make any payment, in whole or in part, or set off from any payment, otherwise payable to the Contractor under this Agreement, or because of subsequently discovered evidence or the results of subsequent inspections or tests, nullify any previous payment, an amount to be determined by OPG on account of:

1. Work required to be performed prior to a progress payment, including previous progress payments, that has not been entirely performed;

2. Work or the Tunnel Facility Project being Defective, in whole or in part;

3. OPG having corrected or replaced a Defective part of the Work or Tunnel Facility Project in accordance with this Agreement;

4. Losses suffered or incurred by any member of the OPG Group or claims, demands, actions, suits or proceedings for Losses having been made against a member of the OPG Group by any Person in respect of which the Contractor is required to indemnify under this Agreement;

5. a Lien having been filed in respect of the Work or Goods (except to the extent that the Contractor has delivered to OPG a specific security instrument, satisfactory to OPG, to secure the discharge of such Lien) and any Losses incurred by OPG in respect of such Lien;

6. the Contract Price having been reduced;
any other terms of this Agreement or rights under Applicable Law entitling OPG to a set off against the amount for which Application for Payment was made; or

Contractor’s failure to deliver the substitute bond to OPG prior to the 30th day after the maintenance bond is cancelled for any reason or the surety issuing such bond is declared bankrupt, becomes insolvent, ceases to carry on any active business in Ontario or otherwise ceases to meet the requirements of this Agreement, as more particularly described in Section 4.1(c).

7.4 Title Warranty

(a) **Warranty.** The Contractor represents and warrants to OPG that title to all Work (including documents, designs, drawings, specifications, plans, reports, information and other deliverables and data) and Goods (excluding the TBM) covered by any Application for Payment, whether used or incorporated in the Project or not and wherever situate, will pass to OPG no later than the time of payment, free and clear of all Liens. OPG’s retention of any amount under Sections 7.3(c), 7.3(f) or 7.5(e) will in no way affect the Contractor’s representation and warranty in this Section 7.4(a), and for the purposes of this Section 7.4(a), OPG will be deemed to have paid each approved Application for Payment in full upon any payment required under Section 7.3(b) having been made.

(b) **Maintenance of Records.** The Contractor will compile and maintain at the Site, in accordance with the Final Submittals and Applicable Laws, detailed, itemized records of all items covered by each Application for Payment, including all Work (including documents, designs, drawings, specifications, plans, reports, information and other deliverables and data) and Goods. On request by OPG, the Contractor will promptly provide OPG access to such records for review and copying. The Contractor will maintain these records for the period expiring on the latest of:

1. seven years following expiration or termination of this Agreement;
2. the period of time as may be specified in this Agreement, including the Contractor’s Proposal Documents or the Final Submittals;
3. the period of time as may be required by Applicable Laws; and
4. such other period as OPG may set out in a Notice to the Contractor.

7.5 Taxes

(a) **Goods and Services Tax.** The Contractor represents and warrants to OPG that, for any goods and service tax invoiced to OPG, the Contractor will be duly registered for the purposes of Part IX of the *Excise Tax Act* (Canada) and that the
Contractor will provide OPG with its registration number once available. The Contractor will deduct all Canadian goods and services tax levied under the *Excise Tax Act* (Canada) recovered or recoverable by the Contractor on the payment of expenses before submitting any Application for Payment to OPG covering any such expenses.

(b) **Provincial Sales Tax.**

(1) All amounts payable by OPG to the Contractor pursuant to this Agreement include any Ontario Retail Sales Tax payable pursuant to Applicable Law by the Contractor in respect of the Work but do not include any Ontario Retail Sales Tax payable pursuant to Applicable Law by OPG.

(2) OPG represents, warrants, and covenants to the Contractor that any electrical generating equipment that is acquired for incorporation into the Work is exempt from Ontario Retail Sales Tax pursuant to Section 7(1)(40) of the *Retail Sales Tax Act* (Ontario) and, accordingly, no Ontario Retail Sales Tax is payable pursuant to Applicable Law by the Contractor in respect of any such Goods or equipment that is acquired for incorporation into the Work. In addition, OPG has applied for and received retail sales tax ruling letters from the Ontario Ministry of Finance that set out certain Goods and equipment that when acquired by the Contractor for incorporation into the Work are exempt from Ontario Retail Sales Tax (all such ruling letters are attached hereto as Appendix Appendix 7.3(b)). The Contractor represents, warrants, and covenants to OPG that to the extent that these rulings indicate that the Contractor may acquire the particular Goods and equipment covered by the rulings exempt from the Ontario Retail Sales Tax Act by providing the supplier of the particular Goods or equipment with a properly completed Ontario Retail Sales Tax Purchase Exemption Certificate, the Contractor has calculated the Contract Price on the basis that the Contractor will acquire such Goods and equipment exempt from Ontario Retail Sales Tax and the Contractor will provide such supplier(s) with a properly completed Ontario Retail Sales Tax Purchase Exemption Certificate(s). If the Ontario Ministry of Finance at any time revokes any of the rulings, determines that any Goods or equipment acquired by the Contractor exempt from Ontario Retail Sales Tax did not qualify as electrical generating equipment acquired for incorporation into the Work, or determines that any of the rulings are not binding, OPG will indemnify and hold harmless the Contractor for any Ontario Retail Sales Tax, penalties, interest, and other costs payable by the Contractor as a consequence.

(3) With respect to the TBM, OPG represents, warrants and covenants to the Contractor that pursuant to the *Retail Sales Tax Act* (Ontario) and the regulations promulgated thereunder (collectively, the “RSTA”), regardless of the fact that legal title to the TBM will be transferred by the Contractor to OPG pursuant to this Agreement, the Contractor will be considered to
be the “purchaser” of the TBM for RSTA purposes and, accordingly, (a) the Contractor is required to pay Ontario Retail Sales Tax on its costs of acquiring and commissioning the TBM, (b) the Contractor is not required to charge and collect Ontario Retail Sales Tax from OPG in respect of that portion of the Contract Price allocated to the TBM, and (c) the Contractor is not required to pay Ontario Retail Sales Tax when legal title to the TBM is transferred back to the Contractor from OPG as contemplated by this Agreement. Accordingly, the Contractor has determined the Contract Price and, more specifically, that portion of the Contract Price allocated to the TBM, on the basis that the Contractor will be required to pay Ontario Retail Sales Tax on its costs of acquiring and commissioning the TBM. If at any time it is determined that OPG is or was the “purchaser” of the TBM for RSTA purposes and OPG is assessed for failure to pay Ontario Retail Sales Tax in respect of that portion of the Contract Price allocated to the TBM, OPG shall pay the assessment, the Contractor shall apply for a refund of the Ontario Retail Sales Tax that it paid in respect of its acquisition and commissioning of the TBM, and the Contractor shall pay any such refund (and interest thereon) received to OPG as a reduction to the Contract Price. If at any time it is determined that OPG is or was the “purchaser” of the TBM for Ontario Retail Sales Tax purposes and the Contractor is assessed for failure to charge and collect Ontario Retail Sales Tax from OPG, OPG shall indemnify and hold harmless the Contractor for any Ontario Retail Sales Tax, penalties, interest and other costs incurred or payable by the Contractor as a consequence of or in respect of any such assessment. OPG shall indemnify and hold harmless the Contractor for any Ontario Retail Sales Tax, penalties, interests and other costs incurred or payable by the Contractor as a consequence of any of these representations, warranties and covenants by OPG regarding the TBM and Ontario Retail Sales Tax being inaccurate or in error.

(4) If the Contractor is a non-resident of Ontario, the Contractor will comply with Section 39 of the RSTA and provide OPG with a duplicate copy of an applicable letter of compliance issued by the Ministry of Finance (Ontario) certifying that the Contractor has satisfied this requirement. In the event that OPG is not provided with a duplicate copy of an applicable letter of compliance, the Contractor acknowledges that OPG has an obligation to withhold and remit to the Minister of Finance (Ontario) 4% of all amounts payable to the Contractor.

(5) The indemnities contained in Section 7.5 of this Agreement shall not merge and shall survive termination or expiration of this Agreement indefinitely.

(c) **The Contractor’s Income Taxes and Withholdings.** OPG will have no liability for:
Refund of Taxes. All remissions or refunds of any Taxes (other than income or capital (including large corporations)), paid or payable by any Governmental Authority in respect of the Work, in whole or in part, are the exclusive property of OPG. All amounts received by the Contractor or a Subcontractor by way of a remission or refund of any Taxes will constitute trust monies to which OPG is exclusively entitled. The Contractor will promptly forward all such amounts to OPG. The Parties will co-operate with each other and take all actions required or desirable to apply for any applicable remission or refund of Taxes. Upon request by OPG, the Contractor will execute, or cause any Subcontractor to execute, all required or desirable documentation to allow OPG to act in the name of the Contractor or a Subcontractor, as the case may be, to apply for and receive any such remission or refund. OPG may be entitled to a rebate under the Retail Sales Tax Act (Ontario), for retail sales tax paid in connection with this Agreement. The Contractor will show, in the manner directed by OPG, on each Application for Payment, either the actual Ontario retail sales tax paid by the Contractor by category or the portion of the Contract Price eligible under Applicable Law for the rebate.

Withholding for Non-residents. Notwithstanding any term in this Agreement, OPG may withhold any amount that is required to be withheld by any Applicable Laws respecting Taxes. OPG will have no obligation to gross up or otherwise increase payments made to the Contractor or any Subcontractor because OPG withheld any amount in respect of Taxes. Where OPG so withholds any amount, OPG will remit such amount to the applicable Governmental Authority. If OPG is entitled to set off an amount owing by OPG under this Agreement against an amount owing to OPG under this Agreement and OPG is also required to withhold an amount under any Applicable Laws respecting Taxes, then OPG will set off an amount owing by OPG against an equal amount owing to OPG. For example, if OPG owes the Contractor $100 and of that amount OPG is required to withhold $15, and the Contractor owes OPG $95, then:

1. OPG would withhold and remit to the Canada Revenue Agency $15; and
2. the Contractor would pay OPG $10.

These payments would thus entirely extinguish both OPG’s obligation to the Contractor and the Contractor’s obligation to OPG.

Importer of Record. If any portion of the Goods is to be manufactured or fabricated outside Canada, the Contractor will ensure that either the Contractor or
its agent will be the importer of record for customs purposes. OPG will reimburse the Contractor for Canadian goods and services tax paid to obtain customs clearance upon written request with sufficient supporting information provided the Contractor is a non-resident and not registered for Part IX of the Excise Tax Act (Canada).

7.6 **Contract Price Fixed**

Subject to changes in the Contract Price made in accordance with Section 7.7(a), the Contract Price is fixed and constitutes the total compensation payable to the Contractor for performing and entirely finishing the Work. In particular, the Contract Price includes all Work (including all costs respecting the provision of labour and benefits, and the associated administration and approval processes, construction equipment and tools, and including the daily travel and subsistence allowance payable for construction labour and the associated administration and approval processes for processing the employee requests under the applicable terms of the applicable construction collective agreements), freight (delivered duty paid, as that term is defined in the Incoterms 2000), Taxes (except for Canadian goods and services tax levied under the Excise Tax Act (Canada)), currency exchange risk and costs, insurance required to be provided by the Contractor and all other costs and expenses of every kind respecting the Work under this Agreement. The Contract Price does not include, however, Canadian goods and services tax levied under the Excise Tax Act (Canada).

7.7 **Changes in Contract Price**

(a) **Changing Contract Price.** The Contract Price may only be changed by an Amendment made in accordance with Section 5. No other purported change to the Contract Price will be valid.

(b) **Pricing Changes to Contract Price.** If a Project Change Directive will have the effect of changing the Contract Price, the Parties will change the Contract Price by an Amendment made in accordance with Section 5 by application of:

(1) a mutually agreed lump sum based on Section 7.8; or

(2) to the extent that Section 7.7(b)(1) is not applicable, cost reimbursement based on Section 7.8.

7.8 **Cost Reimbursement for Changes in the Work**

(a) **Costs to Include in Calculating Value in Change in the Work.** Where the Parties calculate the amount of the costs applicable to any change in the Work under this Section 7.8, the Parties will calculate all the applicable amounts under Sections 7.8(a) and 7.8(c) without duplication, but will not include any amounts for items under Section 7.8(b). Notwithstanding any term in this Section 7.8, no amount calculated under Sections 7.8(a) or 7.8(c) will exceed the applicable amounts then prevailing in the locality of the performance of the applicable Work. The terms of this Section 7.8 apply equally whether the amount of the Work is being increased or decreased due to the change in the Work.
1) **Payroll Costs of Labour.** In calculating the amount of the costs applicable to any change in the Work, the Parties will calculate the payroll costs, including shift and overtime premiums, for hourly paid union labour in the direct employ of the Contractor that would be involved in providing the increase and/or decrease in Work. Such payroll amounts will be determined under the applicable terms of the applicable collective agreements. Such payroll costs include all contributions, premiums, allowances and remittances due to any Governmental Authority, travel and subsistence costs, pension fund, benefit plan, or union fund in accordance with a collective agreement and all Canada Pension Plan contributions, employment insurance premiums and Workplace Safety and Insurance Board premiums. Notwithstanding any term in this Section 7.8, under no circumstance will OPG pay, or otherwise be liable for, any tax equalization payment respecting any Person performing any of the Work.

2) **Work of Subcontractors.** In calculating the amount of the costs applicable to any change in the Work, the Parties will calculate the actual purchase cost to the Contractor, net of discounts, rebates and other refunds, of the increase and/or decrease in the applicable Work performed by a Subcontractor.

3) **Professional Services.** To the extent that the changes in the Work require specific Professional Services, the rates payable therefore shall be subject to review and approval of OPG prior to undertaking any change in the Work.

4) **Purchased Goods.** Subject to Section 7.8(b)(2), in calculating the amount of the costs applicable to any change in the Work, the Parties will calculate the actual purchase cost to the Contractor, net of discounts, rebates and other refunds and returns from the sale of surplus Goods, of the increase and/or decrease in the applicable Goods, delivered to the Site.

5) **Rented Construction Equipment.** Subject to Section 7.8(b)(2), in calculating the amount of the costs applicable to any change in the Work, the Parties will calculate the actual rental cost to the Contractor, net of discounts, rebates and other refunds, of the increases and/or decreases in the applicable rented construction equipment, delivered to the Site. The rental costs may not exceed the lesser of the Contractor’s rental rates or the rates set out in the latest edition of the Ontario Provincial Standards, OPSS 127 Schedule of Rental Rates for Construction Equipment. All rental rates will be subject to approval by OPG and will exclude the cost of the operator. For utilization in excess of 8 hr/day or 176 hr/mo, or for standby charges, or for transportation to and from the Site, reduced rates shall apply and shall be as agreed by OPG.

6) **Owned Construction Equipment.** Subject to Section 7.8(b)(2), in calculating the amount of the costs applicable to any change in the Work,
the Parties will calculate the cost to the Contractor of the increases and/or decreases in the applicable construction equipment owned by the Contractor or one of its affiliates, delivered to the Site. The costs may not exceed the lesser of the Contractor’s rates or the rates set out in the latest edition of the Ontario Provincial Standards, OPSS 127 Schedule of Rental Rates for Construction Equipment. All such charge rates shall be subject to approval by OPG and shall exclude cost of operator. For utilization in excess of 8 hr/day or 176 hr/mo, or for standby charges, or for transportation to and from the Site, reduced rates shall apply and shall be as agreed by OPG.

(7) **Taxes.** In calculating the amount of the costs applicable to any change in the Work, the Parties will calculate the actual cost of additional or reduced Taxes, excluding income and capital (including large corporations) taxes and goods and services tax levied under the *Excise Tax Act* (Canada).

(8) **Unit Rates.** To the extent that the changes in the Work require changes in costs in respect of those elements of the Work identified under the heading “Unit Rates” in Appendix 1.1(j), in calculating such changes in costs, the Parties will use the unit rates set out in Appendix 1.1(j) for such elements of the Work. For such elements of the Work the adjusted costs calculated by using such unit rates shall be the only changes in the cost applicable to such elements of the Work and any other costs shall be excluded.

(b) **Costs to Exclude in Calculating Value in Change in the Work.** Notwithstanding any term in Section 7.8(a), where the Parties calculate the amount of the costs applicable to any change in the Work, the Parties will exclude the costs of each of the amounts set out in this Section 7.8(b).

(1) **Payroll Costs of Supervisors and Management.** In calculating the amount of the costs applicable to any change in the Work, the Parties will exclude all payroll costs, additives and other costs respecting individuals not included under Section 7.8(a)(1), including supervisors, managers, superintendents, engineers and other design Professionals directly employed by the Contractor (except to the extent directly required to make the change in the Work), architects, estimators, accountants, lawyers, auditors, purchasing and contracting agents, field engineers, expediters, timekeepers, clerks, officers, directors and partners, whether on or off the Site. The costs of all such individuals are considered to be administrative costs covered under Section 7.8(c).

(2) **Overhead and Profit Fee.** In calculating the amount of the costs applicable to any change in the Work, any overhead or profit fee of any Subcontractor of any tier. The Contractor will be responsible for paying any such overhead or profit fees from any overhead and profit fee paid to the Contractor under Section 7.8(c).
(3) **Specified Construction Equipment.** In calculating the amount of the costs applicable to any change in the Work, the Parties will exclude all construction equipment and tools having a replacement cost, or with a base rental price, of less than $2,500, exclusive of all Taxes.

(4) **Specialized Tunneling Equipment.** In calculating the amount of the costs applicable to any change in the Work, ownership or rental costs, including but not limited to excess utilization or standby costs for specialized tunneling equipment, including but not limited to the TBM, trailing gear, tunnel mucking equipment, and grouting equipment. Such cost will be deemed to have been adequately provided for and included elsewhere in the contract lump sums.

(5) **Office Costs.** In calculating the amount of the costs applicable to any change in the Work, the Parties will exclude all costs respecting the Contractor’s offices, whether on or off the Site.

(6) **Capital Costs.** In calculating the amount of the costs applicable to any change in the Work, the Parties will exclude:

(A) any debt carrying charges, including principal payments, interest or other carrying charges; and

(B) all capital costs, including interest, on the Contractor’s capital employed for the Work and charges against the Contractor for late payments, if any.

(7) **Negligence.** In calculating the amount of the costs applicable to any change in the Work, the Parties will exclude all costs incurred as a result of negligence of the Contractor, any Subcontractor, any member of the Contractor’s Personnel or any of the Contractor’s or any of a Subcontractor’s shareholders, directors, officers, partners, members, representatives, agents, advisors or any other Person for whom the Contractor or any Subcontractor is responsible at law, including any costs of any claims, demands, actions, suits or proceedings for Losses made by any Person and the costs respecting the correction or replacement of the Defective part of the Work, the disposal of Goods incorrectly purchased or the correction of any damages.

(8) **Other Costs.** In calculating the amount of the costs applicable to any change in the Work, the Parties will exclude all other costs not expressly set out in Sections 7.8(a) or 7.8(c), including all indemnifications by the Contractor under this Agreement, all costs of all acts that are to be provided at the expense of the Contractor under this Agreement and all costs which are recoverable by the Contractor in respect of warranties, guarantees, insurance or other security (including performance related security) in favour of the Contractor or a Subcontractor.
(c) **Overhead and Profit Fee.** Where the Parties calculate the amount of the costs applicable to any change in the Work, the Parties will include or deduct the additional fee, representing the Contractor’s supervision, overhead (including salary burdens and small tools), profit and all other costs. Such fee will be calculated as follows:

1. for additional costs incurred under Section 7.8(a)(1), the Contractor’s fee will be 10% of such costs;
2. for additional costs incurred under Sections 7.8(a)(2) and 7.8(a)(5), the Contractor’s fee will be 10% of such costs;
3. for additional costs incurred under Sections 7.8(a)(4) and 7.8(a)(6), the Contractor’s fee will be 5% of such costs;
4. for Section 7.8(a)(7), nil;
5. where one or more tiers of Subcontractors are reimbursed for additional costs on the basis of cost of the Work plus a fee, the intent is that the Subcontractor who performs the Work, at whatever tier, will be paid a fee of 10% of the costs incurred by such Subcontractor under Section 7.8(a)(2). Any higher tier Subcontractor and the Contractor will each be paid a fee of 5% of the cost amount only paid to the next lower tier Subcontractor in accordance with the provisions of Section 7.8(b)(2);
6. the amount of credit to be allowed by the Contractor to OPG for any change which results in a net decrease in cost as calculated under Section 7.8(a) will be the amount of the actual net decrease in cost plus a deduction in the Contractor’s fee by an amount equal to 5% of such net decrease; and
7. when both additions and credits are involved in any one change, the adjustment in the Contractor’s fee shall be computed in accordance with Sections 7.8(c)(1) through 7.8(c)(6) above, and will be based on the aggregate net cost of the change calculated in accordance with Section 7.8(a).

(d) **Documentation and Readjustment.** Where any calculations are made under this Section 7.8, OPG may, at any time, require from the Contractor satisfactory evidence of any cost figures supplied by the Contractor. OPG may have any such cost figures reviewed by auditors designated by OPG, so long as OPG directs such review to be performed within two years after the Final Completion Date. The Contractor will provide such auditors prompt access to all premises and documents required for such review. The Contractor will preserve all records necessary for any such calculation until the end of such two-year period. If the Contractor fails to preserve any such records, OPG may make any reasonable assumptions in the absence of such records. All payments made by OPG involving calculations under this Section 7.8 are subject to readjustment based on
any such audit at any time before the expiry of the 26th month after the Final Completion Date.

7.9 Substantial Completion

(a) Notice of Ready for Use. The Contractor will deliver a Notice in the form attached as Appendix 7.9(a) to OPG (including a punch list of all items that remain unfinished and which will not impair the intended use of the Tunnel Facility Project and a schedule for entirely finishing each such item) when:

1. “substantial performance” has occurred, as such term is defined in the Construction Lien Act (Ontario);

2. the Work has progressed to the point where the Tunnel Facility Project is ready for use and is sufficiently complete, in accordance with this Agreement, so that the Tunnel Facility Project may be used as intended in accordance with this Agreement;

3. the cost to entirely finish the Work that remains unfinished and to correct any known Defective parts of the Work does not exceed a total of $4 million;

4. the Contractor has obtained and delivered to OPG the Approvals which the Contractor is required to obtain under Section 2.6(b);

5. the Tunnel Facility Project has been commissioned and meets all of the tests set out in the Final Submittals and this Agreement;

6. water is flowing in the tunnel, with gates fully open, unrestricted between tunnel intake and outlet structure for a continuous period of 24 hours, provided that the Contractor will not water up the tunnel unless the tunnel is free of Defects, and provided that all other material obligations under this Agreement have also been satisfied;

7. the Contractor has delivered to OPG copies of all certified reports of the performance tests described in this Section 7.9(a); and

8. the Contractor has delivered to OPG an affidavit of each of the Contractor’s design Professionals substantially in the form attached as Appendix 7.9(a)(8).

When OPG determines, acting reasonably, that all of the terms of Sections 7.9(a)(1) to 7.9(a)(8) inclusive have been complied with then “Substantial Completion” has occurred.

(b) Joint Inspection. Within a reasonable time after receipt of the Notice under Section 7.9(a), the Parties will make a joint inspection of the Tunnel Facility Project to determine the status of the Tunnel Facility Project and each outstanding
item, including each item set out in the Notice delivered under Section 7.9(a). If OPG determines that Substantial Completion has not occurred in accordance with Section 7.9(a), OPG will deliver a Notice in the form of document attached as Appendix 7.9(b) to this effect to the Contractor, giving reasons. If OPG determines that Substantial Completion has occurred in accordance with Section 7.9(a), OPG will deliver a Notice in the form of document attached as Appendix 7.9(b) containing a certificate of Substantial Completion. This certificate will fix the date of Substantial Completion. The Parties will then sign a certificate of substantial completion as contemplated by Section 32(1)(1) of the Construction Lien Act (Ontario). The Contractor will then promptly publish the notice in accordance with the Construction Lien Act (Ontario).

(c) **Punch List and Allocation of Responsibilities.** OPG will attach to the certificate of Substantial Completion a punch list of items that are to be entirely finished or are Defective and must be corrected or replaced by the Contractor before final payment will be made under Section 7.12. At the time of delivery of the certificate of Substantial Completion OPG will also deliver to the Contractor a written allocation of responsibilities between OPG and the Contractor pending final payment made under Section 7.12 respecting safety, security, operation, maintenance, insurance and warranties and guarantees respecting the remaining Work. The Contractor will deliver a Notice to OPG each week setting out an update as to the status of completion of each punch list item.

(d) **Access to Perform Remaining Obligations.** OPG may exclude the Contractor from the Site, in whole or in part, after the date of Substantial Completion. OPG will, however, allow the Contractor reasonable access to such parts of the Site as are required to permit the Contractor to finish entirely or correct all items on the punch list.

### 7.10 Final Inspections

When the Contractor considers that it has entirely finished or corrected all items on the punch list, the Flow Verification Test has been conducted and the final Test report has been approved by the chief of test and delivered to OPG and the Contractor (as more particularly described in Section 11 of Appendix 1.1(aa)), the Contractor may deliver a Notice to this effect to OPG. Promptly following receipt of this Notice, the Parties will make a joint inspection of the Tunnel Facility Project. OPG will then deliver a Notice in the form attached as Appendix 7.10 to the Contractor stating either that:

(a) OPG accepts the Work as being entirely finished, including because the Contractor has delivered to OPG all Approvals and other written or graphic documents, designs, drawings, specifications, plans, reports, information and other deliverables or data required to be provided by the Contractor to OPG under this Agreement and because the Contractor has satisfied all requirements of Applicable Laws; or
(b) there are items remaining to be entirely finished or that are Defective and must be corrected or replaced by the Contractor. The Contractor will promptly take such actions as are necessary to finish entirely, correct or replace all such items. Once the Contractor has finished all such actions, the Contractor will deliver another Notice to OPG in accordance with this Section 7.10.

7.11 Final Application for Payment

After OPG has accepted the Work as being entirely finished under Section 7.10(a), the Contractor may make a final Application for Payment in accordance with Section 7.2. The Contractor will submit with the final Application for Payment (except to the extent previously delivered by the Contractor and accepted by OPG as satisfactory), the following:

(a) as-built drawings, maintenance and operating instructions, security documents, certificates of insurance, certificates of inspection, all documents required to be maintained at the Site in accordance with Section 2.15(a) and all other documents required by this Agreement to be delivered to OPG on the entire finishing of the Tunnel Facility Project;

(b) the required consent of any surety, if any, to the final payment made under Section 7.12;

(c) a certificate of good standing from the Workplace Safety and Insurance Board or successor organization;

(d) releases in the form set out in Appendix 7.11, from the Contractor and each Subcontractor who performed Work in respect of the Tunnel Facility Project, respecting all Liens and other claims filed or otherwise arising in respect of the Work or Tunnel Facility Project; and

(e) statutory declarations in the form set out in Appendix 7.11, signed by a director or officer of the Contractor, and each Subcontractor who has performed Work at the Site, declaring that all payments due to Subcontractors, all wages and benefit payments due to any of the Contractor’s Personnel, and all contributions, premiums, allowances and remittances due to any Governmental Authority, pension fund, benefit plan, or union fund in accordance with a collective agreement, have been paid in a timely manner.

If the Contractor is unable to deliver to OPG any release or statutory declaration referred to in Sections 7.11(d) and 7.11(e) from a Subcontractor, the Contractor will deliver to OPG collateral or security satisfactory to OPG to indemnify OPG against any Lien or other claim until such time that any Lien or claim would expire by operation of Applicable Laws.

7.12 Final Payment and Acceptance

On receipt of the Application for Payment under Section 7.11, OPG will review the Application for Payment within 10 Business Days after receipt and deliver a Notice in the form attached as Appendix 7.12 to the Contractor stating either that:
(a) OPG accepts the Application for Payment and OPG will make, subject to Sections 7.3(f) and 7.5(c), the final payment within 60 days after the delivery of such Application for Payment to OPG; or

(b) the Application for Payment does not yet satisfy all the obligations under this Agreement and setting out the reasons therefore. The Contractor will promptly take such actions as are necessary to satisfy its remaining obligations. Once the Contractor has satisfied all such obligations, the Contractor will deliver to OPG an amended final Application for Payment under Section 7.11.

Where OPG makes the final payment to the Contractor under this Section 7.12, such payment will not relieve the Contractor from any of its obligations or liabilities under this Agreement or otherwise. To the extent that any of the Work was not performed on a fixed fee basis, the Contractor will maintain the applicable records, including time sheets, accounts and invoices, for seven years following expiration or termination of this Agreement, or for such other period as OPG may set out in a Notice to the Contractor. On request by OPG, the Contractor will promptly provide OPG access to such records for review and copying.

7.13 Adjustment for Labour Rates

OPG and the Contractor acknowledge and agree that:

(a) as of the date of this Agreement, a new collective agreement has not been finalized with the unionized building trades who are members of the Canadian Union of Skilled Workers (“CUSW”);

(b) as of the date of this Agreement, the unionized building trades who are members of the Electrical Power Systems Construction Association (“EPSCA”) and the Brick and Allied Craft Union of Canada (“BACU”) have negotiated hourly wage rates for the first 3 years of their collective agreements commencing May 1, 2004, such wage rates are listed in Appendix 7.13(b);

(c) in calculating the Contract Price, the Contractor has assumed the following hourly wage rate increases for trades performing Work on Site (collectively the “Assumed Rates”):

For CUSW, the Assumed Rates were calculated as follows for the periods indicated:

• $1.20 per hour increase above the 2003 CUSW hourly wage rate for the period commencing May 1, 2004, and ending April 30, 2005 (the “2004 CUSW Rate”);

• $1.10 per hour increase above the 2004 CUSW Rate for the period commencing May 1, 2005, and ending April 30, 2006 (the “2005 CUSW Rate”);

• $1.10 per hour increase above the 2005 CUSW Rate for the period commencing May 1, 2006 and ending April 30, 2007; and
• 3% increase above the CUSW hourly wage rate from the immediately preceding year for each year (or part year) of the Agreement commencing from and after May 1, 2007;

For EPSCA and BACU, the Assumed Rates were calculated as follows for the periods indicated:

• increases of 3% above the EPSCA or BACU, as the case may be, hourly wage rate from the immediately preceding year for each year (or part year) of the Agreement commencing from and after May 1, 2007;

(d) on or prior to the Final Completion Date, the Contractor will provide to OPG a Notice setting out the actual hourly wage rates in effect for the relevant periods as agreed to by CUSW, EPSCA and BACU (collectively the “Actual Rates”) together with any supporting documentation required by OPG. Such Notice will set out, on a trade by trade and month by month basis, the differences between the Actual Rates and the Assumed Rates for the relevant periods (the “Rate Differentials”);

(e) upon receipt of such Notice, OPG will calculate, on a trade by trade and month by month basis, the product obtained by multiplying the relevant Rate Differential by the aggregate number of man hours set out in the Man-Hour Breakdown for the relevant trades for the relevant period (for each trade on a month-by-month basis, a “Trade Product”). OPG will provide a Notice to the Contractor, which Notice will set out the Trade Product for each trade on a month-by-month basis and the net amount of all Trade Products (the “Rate Adjustment Amount”). If the Rate Adjustment Amount is positive, the Contractor will include as part of the final Application for Payment an amount equal to the Rate Adjustment Amount. If the Rate Adjustment Amount is negative, the Contractor will deduct from the final Application for Payment an amount equal to the Rate Adjustment Amount. If the Rate Adjustment Amount is greater than the amount to be paid in connection with the final Application for Payment, no final payment will be made to the Contractor and the Contractor will forthwith pay to OPG an amount equal to such difference;

(f) all references to hourly wage rates in this Section refer to hourly wage rates, including payroll burden and excluding all other costs, such as travel and subsistence allowance; and

(g) the Man-Hour Breakdown shall be submitted as a Submittal within 90 days after the Start Date.

SECTION 8. PERFORMANCE INCENTIVES

8.1 Calculation of Liquidated Damages for Delay

Subject to the maximum liquidated damages set out in Section 8.5, the Contractor will pay OPG (by means of set off from the total amount due to the Contractor under this Agreement or, if
insufficient amounts are due, by payment by the Contractor) the following sums for each complete day that the day fixed for Substantial Completion under Section 7.9(b) falls after the date for Substantial Completion set out in the Contract Schedule:

(a) the sum of $250,000 per day during the period November to March inclusive; and

(b) the sum of $180,000 per day during the period April to October inclusive.

The Parties acknowledge that the precise amount of actual damages would be extremely difficult to calculate and that the amount of damages for failure to achieve Substantial Completion in accordance with the Contract Schedule as provided for in this section represents a reasonable and genuine pre-estimate of actual damages and is not a penalty.

### 8.2 Calculation of Bonus for Early Substantial Completion

Subject to the maximum bonus set out in Section 8.6, OPG will pay the Contractor the following sum for each complete day that the day fixed for Substantial Completion under Section 7.9(b) falls before the date for Substantial Completion set out in the Contract Schedule:

(a) the sum of $125,000 per day during the period November to March inclusive; and

(b) the sum of $90,000 per day during the period April to October inclusive.

Notwithstanding the foregoing, no amount shall be payable to the Contractor by OPG under this Section 8.2 until the calculations relating to liquidated damages under Section 8.3 and relating to bonuses under Section 8.4 are complete.

### 8.3 Calculation of Liquidated Damages Related to Guaranteed Flow Amount

Within 2 weeks following Substantial Completion, the Contractor will arrange for the performance of the water flow performance test in accordance with the Flow Verification Test set out in Appendix 1.1(aa). OPG shall have the right to be represented at such test and shall have access to all data resulting from such test.

Subject to the maximum liquidated damages set out in Section 8.5, within 30 days of the date of the water flow performance test, the Contractor will pay OPG (by means of set off from the total amount due to the Contractor under this Agreement or, if insufficient amounts are due, by payment by the Contractor) the following sum for the difference in water flow calculated as follows:

\[
PTWFA = \text{Performance Test Water Flow Amount (performed and adjusted in accordance with Flow Verification Test, expressed in m}^3/\text{s)}
\]

\[
GFA = \text{Guaranteed Flow Amount (expressed in m}^3/\text{s)}
\]

\[
GFA - PTWFA = A
\]

\[
0.02 = \text{Assumed Flow Amount +/- 2% Test Uncertainty}
\]
(a) If “A” is positive and equal to or less than (PTWFA x 0.02), or if “A” is zero, no liquidated damages are due under this Section 8.3;

(b) If “A” is negative, the Contract may be entitled to a bonus as calculated in Section 8.4;

(c) For the portion of “A” greater than (PTWFA x 0.02), the amount of such portion shall be multiplied by the following sums within the specified ranges:

1. $350,000 for each 1 m$^3$/s of incremental flow from 600 to 650 m$^3$/s, inclusive
2. $390,000 for each 1 m$^3$/s of incremental flow from 550 to 600 m$^3$/s, inclusive
3. $430,000 for each 1 m$^3$/s of incremental flow from 500 to 550 m$^3$/s, inclusive
4. $600,000 for each 1 m$^3$/s of incremental flow from 400 to 500 m$^3$/s, inclusive
5. $900,000 for each 1 m$^3$/s of incremental flow from 350 to 400 m$^3$/s, inclusive
6. $1,800,000 for each 1 m$^3$/s of incremental flow less than 350 m$^3$/s.

The Parties acknowledge that the precise amount of actual damages would be extremely difficult to calculate and that the amount of damages for failure to achieve GFA as provided for in this section represents a reasonable and genuine pre-estimate of actual damages and is not a penalty.

The amount of liquidated damages payable under this Section 8.3 shall be the sum of the amounts calculated under the applicable Section 8.3(c)(1) to 8.3(c)(6), inclusively, above.

Example: If the Guaranteed Flow Amount is 560 m$^3$/s and the Performance Test Water Flow Amount is 500 m$^3$/s, then the liquidated damages payable would be based on 60 m$^3$/s - (500 m$^3$/s x 0.02) = 50 m$^3$/s. The calculation would be ((40 x $430,000) + (10 x $390,000)) = $21,100,000 (liquidated damages).

### 8.4 Calculation of Bonuses Related to Guaranteed Flow Amount

Subject to the maximum bonus set out in Section 8.6, within 30 days of the date of the water flow performance test, OPG will pay the Contractor the following sum for the difference in water flow calculated as follows (using the value for “A” calculated in Section 8.3):

(a) If “A” is negative and the absolute value of “A” is equal to or less than (PTWFA x 0.02), no bonus is due under this Section 8.4.
If “A” is negative and the absolute value of “A” is greater than (PTWFA x 0.02), for the portion of “A” that is greater than (PTWFA x 0.02), the amount of such portion shall be multiplied by the following sums below within the specified ranges:

1. $175,000 for each 1 m³/s of incremental flow from 600 to 650 m³/s, inclusive
2. $195,000 for each 1 m³/s of incremental flow from 550 to 600 m³/s, inclusive
3. $215,000 for each 1 m³/s of incremental flow from 500 to 550 m³/s, inclusive
4. $300,000 for each 1 m³/s of incremental flow from 400 to 500 m³/s, inclusive
5. $450,000 for each 1 m³/s of incremental flow from 350 to 400 m³/s, inclusive
6. $900,000 for each 1 m³/s of incremental flow less than 350 m³/s.

The total bonus payable under this Section 8.4 shall be the sum of the amounts calculated under the applicable Section 8.4(b)(1) to 8.4(b)(6), inclusively, above.

Example: If the Guaranteed Flow Amount is 520 m³/s and the Performance Test Water Flow Amount is 570 m³/s then the bonus payable would be based on 50 m³/s - (570 m³/s * 0.02) = 38.6 m³/s. The calculation would ((30 m³/s * $215,000) + (8.6 m³/s * $195,000)) = $8,127,000 (Bonus).

8.5 Maximum Liquidated Damages

The total amount of liquidated damages calculated under Sections 8.1 and 8.3 will not exceed 20% of the Contract Price.

8.6 Maximum Bonus Payment

The total amount of the bonus payment calculated under Section 8.2 and 8.4 will not exceed 20% of the Contract Price.

SECTION 9. ACCEPTANCE OF TUNNEL FACILITY PROJECT AND CORRECTION OF DEFECTS

9.1 Warranty

(a) Basic Warranty. The Contractor warrants and guarantees to OPG that:

1. notwithstanding anything else in this Agreement, the Work will in all respects be fit for the purposes intended by this Agreement, including the
Owner’s Mandatory Requirements, Contractor’s Proposal Documents and the Final Submittals; and

(2) all Work will be performed in accordance with this Agreement.

(b) **Exclusions.** The Contractor’s warranties and guarantees in Section 9.1(a) do not apply to the extent that any breach of the warranty or guarantee is due to:

(1) maintenance or operation by OPG contrary to any maintenance or operating instructions delivered by the Contractor to OPG; or

(2) the negligence of OPG or any Person providing services to OPG, other than the Contractor or a Subcontractor.

(c) **No Deemed Acceptance.** The Contractor’s obligations under Section 9.1(a) are absolute. These warranties and guarantees will not be affected in any way by any certificate, acceptance, approval, payment or any other act, matter or thing done or omitted under this Agreement. For greater certainty, none of the following actions will constitute any acceptance of the Work or Tunnel Facility Project by OPG in whole or in part or will constitute a waiver or release of any of the Contractor’s obligations under this Agreement:

(1) any review, comment, acceptance, rejections or failure to review, comment, accept or reject by OPG of a Submittal or other document under this Agreement;

(2) any inspection, test or approval by OPG or any third party;

(3) any payment under this Agreement;

(4) any certificate of Substantial Completion issued under Section 7.9(b);

(5) any use or occupancy of the Tunnel Facility Project in whole or in part by OPG; or

(6) any correction or replacement of a Defective part of the Work or Tunnel Facility Project by, or at the request of, the Contractor, OPG or OPG’s Representative.

(d) **Risk of Loss.** The Work and Tunnel Facility Project will remain at the sole risk of the Contractor against loss or damage up to and including the Final Completion Date (but excluding damage that was caused by OPG and occurred after Substantial Completion to a part of the Work or Tunnel Facility Project for which OPG was responsible at the time the damage occurred).

(e) **Indemnity.** The Contractor will indemnify and hold harmless each member of the OPG Group, from and against:
(1) all Losses suffered or incurred by a member of the OPG Group arising in respect of the Work, to the extent that any such Losses are attributable to bodily injury, sickness, disease or death, or to damage to or destruction of tangible property, including any resulting loss of use; and

(2) all claims, demands, actions, suits or proceedings for Losses made against any member of the OPG Group by any Person,

but only, in each case, to the extent such Losses are caused by:

(i) a breach of this Agreement (including in respect of any breach of Applicable Laws) by the Contractor; or

(ii) by any act or omission of any Person performing any of the Work.

The obligations of the Contractor under this Section 9.1(e) will not be affected in any way by any certificate, acceptance, approval, payment or any other act, matter or thing done or omitted under this Agreement, including any act by OPG or OPG’s Representative referred to in Sections 9.1(c)(1) to 9.1(c)(6) inclusive.

9.2 Access to Tunnel Facility Project

The Contractor will provide access to the Tunnel Facility Project, the Site and the premises of the Contractor and Subcontractors, at all reasonable times and from time to time, to OPG’s Representative, and at the request of OPG’s Representative, to OPG’s Designated Delegates and any other Person, for the purposes of Site visits, compliance with access rights, emergency maintenance and repairs, viewing, performing surveillance on, inspecting, testing and/or accepting the Work and/or Tunnel Facility Project, in whole or in part, including to monitor compliance with the Owner’s Mandatory Requirements, the Contractor’s Proposal Documents, the Final Submittals and any applicable quality assurance program. In particular, the Contractor will deliver a Notice to OPG’s Representative providing OPG with Notice of at least two Business Days before OPG is required to inspect any Goods at any hold point in any inspection plan. At the request of OPG’s Representative, the Contractor will promptly provide to OPG’s Representative a copy of all the documents (unpriced, if the Contractor desires) respecting any subcontract subject to viewing, performing surveillance, inspecting, testing and/or accepting. No such viewing, performing surveillance, inspecting, testing and/or accepting by OPG will relieve the Contractor of any of its obligations or liabilities under this Agreement. The Contractor will advise each applicable representative of OPG of the Contractor’s or Subcontractor’s applicable site safety procedures and policies. The Contractor will provide each such representative with proper and safe transportation and conditions for such access.

9.3 Inspections, Tests and Approvals

The Contractor will with promptness and in an orderly sequence so as not to cause any delay to the Work, arrange for and obtain all inspections, tests and approvals required for the acceptance of Goods that are to be incorporated or used in the Tunnel Facility Project. The Contractor will ensure that each inspection, test or approval that is required to be carried out, in whole or in part, by a Professional, is so carried out by a Professional. The Contractor will pay all costs
respecting such inspections, tests and approvals. If this Agreement, the applicable quality assurance program or any Applicable Laws or Approvals require any part of the Work or the Tunnel Facility Project to be inspected, tested or approved, in whole or in part, the Contractor will arrange for and obtain all such inspections, tests and approvals. The Contractor will pay all costs in connection with such inspections, tests and approvals. The Contractor will deliver to OPG all certificates, reports and other documents respecting any inspections, tests and approvals made in accordance with this Section 9.3, the Contractor’s Proposal Documents or the Final Submittals. The Contractor will give OPG reasonable Notice of the date, time and location for all inspections, tests or approvals carried out under this Section 9.3 so that OPG can attend. If Notice is not given, OPG may require the inspection, test or approval to be redone at the Contractor’s cost. If any such approval is to be issued in the name of OPG or that will affect the operation of the Project following the Final Completion Date, the Contractor will submit the draft approval to OPG’s Representative for acceptance, before the Contractor obtains this approval. The Contractor will only obtain any such approval following receipt of the written acceptance of OPG’s Representative of the draft approval. In addition to any other inspection, test or approval set out in this Agreement, OPG may require, at its cost (but for certainty without payment of any amount to the Contractor), any other inspection, test or approval of any part of the Work or the Tunnel Facility Project, in whole or in part, either on or off the Site, upon Notice to the Contractor.

9.4 Uncovering Project

(a) **Covered Without OPG’s Consent.** If, without the prior written consent of OPG, the Contractor covers any part of the Project (or the construction work of any Person) that is required under this Agreement or Applicable Laws or Approval to be inspected, tested or approved, the Contractor will, at its cost, uncover and recover such part of the Project or construction work. If, however, the Contractor has given OPG timely Notice of the Contractor’s intention to cover such part of the Project or the construction work and OPG has not acted with reasonable promptness in response to such Notice, OPG will be responsible for the cost, calculated in accordance with Section 7.7(b), of uncovering and recovering such part of the Project or the construction work.

(b) **Covered Contrary to OPG’s Request.** If the Contractor covers any part of the Project (or the construction work of any Person) contrary to the request of OPG, the Contractor will, at its cost, if requested by OPG, uncover and recover such part of the Tunnel Facility Project or construction work.

(c) **OPG’s Request to Uncover.** If, for any reason not set out in Sections 9.4(a) or 9.4(b), OPG wishes to have part of the Project uncovered to be inspected, tested or approved by any Person designated by OPG, the Contractor will, at OPG’s request, uncover the requested part of the Project for inspection, testing, approval and performing all necessary Work. If it is determined that any part of the Work uncovered under this Section 9.4(c) is Defective, the Contractor will:

(1) pay all costs for uncovering and recovering the part of the Work requested by OPG to be uncovered;
(2) pay all of OPG’s reasonable costs of inspection, testing and approval; and

(3) correct or replace the Defective part of the Work in accordance with this Section 9.

If, however, it is determined that none of the Work uncovered under this Section 9.4(c) is Defective, OPG will pay all of the Contractor’s reasonable costs for uncovering and recovering the part of the Project requested by OPG to be uncovered, which costs will be calculated in accordance with Section 7.7(b).

9.5 Notice of Defective Tunnel Facility Project

OPG will, within a reasonable period of time after having actual knowledge of a Defective part of the Work, deliver Notice to the Contractor of the Defective part, but OPG’s failure to do so will not impose any liability on OPG and the Contractor will be estopped from making any claim against OPG for failure to do so. In addition, OPG’s failure to do so will not:

(a) have the effect of transferring any obligation under this Agreement from the Contractor to OPG or otherwise have the effect of amending this Agreement; or

(b) will not affect or change in any way the Contractor’s:

(1) obligation to entirely finish the Work in accordance with this Agreement, or

(2) responsibility for repairing, replacing or re-providing any Defective part of the Work or Tunnel Facility Project.

9.6 OPG May Stop Construction

OPG may at any time and from time to time, by delivering a Notice to the Contractor, direct the Contractor to stop the performance of the Work, in whole or in part, including, if

(a) the Work or the Tunnel Facility Project is Defective, in whole or in part;

(b) the Contractor fails to supply suitable Goods, in whole or in part;

(c) the Contractor fails to perform the Work, in whole or in part, in a manner that ensures that the entirely finished Tunnel Facility Project will conform to this Agreement; or

(d) the Contractor has breached any term of this Agreement, including due to any act or omission of a Subcontractor that breaches a term of this Agreement.

The Contractor may resume the stopped Work to which OPG’s direction applies only once the Contractor has remedied the issue that was the cause for OPG to deliver such Notice. OPG is not obliged to deliver a Notice to the Contractor under this Section 9.6 for any reason whatsoever.
Subject to Sections 2.4(i) and 13.1, the Contractor will not be entitled to any change to the Contract Price or the Contract Schedule for any Work stopped pursuant to this Section 9.6.

9.7 Correction or Removal of Defective Part of Tunnel Facility Project - Before Substantial Completion

(a) Work Required. Before Substantial Completion, OPG may accept or reject any Defective parts of the Work or the Tunnel Facility Project, whether or not such part has been incorporated into the Project, on delivery of Notice to this effect to the Contractor. The Contractor will promptly correct all Defective parts of the Work and the Tunnel Facility Project either upon discovery or upon rejection by OPG under this Section 9.7. If reasonably requested by OPG, the Contractor will remove any and all Defective parts of the Tunnel Facility Project from the Site, whether or not such parts have been incorporated into the Project, and replace such parts with parts that are not Defective and that comply with this Agreement.

(b) Cost to Correct or Remove. The Contractor will pay all costs respecting the correction of a Defective part of the Work or the Tunnel Facility Project (“Correction Costs”), including:

(1) all incidental costs of the corrective services, including, as may be required for disassembly, removal, re-installation, re-erection, re-assembly, transportation, insurance and any applicable Taxes;

(2) all of OPG’s fees and charges of engineers, architects, accountants, lawyers (on a solicitor and his own client basis) and other professionals, all court, arbitration and other dispute mediation or resolution costs and charges, whether incurred through settlement or otherwise, together with interest calculated in accordance with Section 1.1(mm); and

(3) all costs and charges respecting correction or replacement of any Defective part of the Work or the Tunnel Facility Project, including any part of the Work or Tunnel Facility Project that was rendered Defective because of the Defective part of the Work or Tunnel Facility Project, including in respect of any damage or loss arising in respect of such correction or replacement or in respect of any inspections conducted to determine whether any such correction or replacement was required, including for loss of use.

9.8 Correction or Removal of Defective Part of Tunnel Facility Project - After Substantial Completion

(a) Warranty Period. “Warranty Period” means, in respect of each part of the Work and Tunnel Facility Project, the greatest of:

(1) one year following the date of Substantial Completion;
(2) the warranty period specified in any warranty from a Subcontractor for any specific part of the Work and Tunnel Facility Project;

(3) the warranty period specified in this Agreement, including the Contractor’s Proposal Documents or the Final Submittals, for any specific part of the Work and Tunnel Facility Project; and

(4) the warranty period for any specific part of the Work and Tunnel Facility Project provided under any Applicable Laws,

subject to any extension made under Section 9.8(d).

(b) **Obligation to Correct.** If at any time and from time to time before the expiration of the relevant Warranty Period, the Work or the Tunnel Facility Project, in whole or in part, including any part of the Work or Tunnel Facility Project that was rendered Defective because of the Defective part of the Work or Tunnel Facility Project, becomes or is determined to be Defective or fails because of any defect, the Contractor will promptly, without cost to OPG and in accordance with OPG’s instructions and at times and within the period of time reasonably specified by OPG:

(1) satisfactorily correct such Defective part of the Work and Tunnel Facility Project, or, to the extent reasonably requested by OPG, remove such Defective part of the Work or Tunnel Facility Project from the Site and replace such Defective part with parts which are not Defective and which comply with this Agreement; and

(2) satisfactorily correct or replace any other damage arising in respect of the actions taken in respect of Section 9.8(b)(1) or in respect of any inspections conducted to determine whether any actions were required in respect of Section 9.8(b)(1).

The Contractor will pay all Correction Costs as described in Section 9.7. In providing any corrective services under this Section 9.8(b), the Contractor will comply with all applicable terms of this Agreement and will endeavour to minimize interference with, and impact on, OPG’s operations.

(c) **Failure to Comply.** If the Contractor fails to comply with its obligations under Section 9.8(b) or any other term in this Agreement as expeditiously as is commercially reasonable and within the time period reasonably specified by OPG, or if there is an emergency that poses a significant risk of loss or damage to the Project or any Person, OPG may take, directly or indirectly, any of the actions contemplated under Section 9.8(b) or such other actions as are reasonable in the circumstances, without affecting any other rights or remedies OPG may have against the Contractor under this Agreement. The Contractor will pay all Correction Costs as described in Section 9.7 respecting all such actions and deduct same from any monies otherwise due, owing or payable to the Contractor.
In respect of any action taken by OPG, directly or indirectly, under this Section 9.8(c), OPG may without terminating this Agreement:

1. eject and exclude from the Site the Contractor, any Subcontractor and any of the Contractor’s Personnel and prohibit the Contractor from continuing the Work;

2. suspend the Contractor’s performance of the Work under this Agreement to the extent of such actions;

3. take possession of the Site, work in progress, Goods, Contractor’s construction equipment, tools, fuel and temporary structures and facilities, including for offices, lunchrooms, canteens, sanitation, showers, change rooms, accommodations, shops, warehouses and garbage disposal, at the Site (and at no additional charge for the retention and use thereof);

4. assume any and all subcontracts with Subcontractors;

5. avail itself of any performance bond, guarantee, indemnity, letter of credit or other security provided by the Contractor or a Subcontractor with respect to the applicable Work;

6. incorporate or use in the Project all Goods stored at the Site or for which OPG has paid the Contractor but which are stored elsewhere, including for greater certainty, the TBM; and/or

7. withhold, without interest, all payments to the Contractor under any agreement between OPG and the Contractor until the Contractor’s liability to OPG is determined.

The Contractor will allow all members of the OPG Group and OPG’s other contractors access to the Site to enable OPG to exercise its rights under this Section 9.8. The Contract Schedule will not be changed for any reason relating to any actions taken by OPG, directly or indirectly, under this Section 9.8(c).

(d) **Extension of Correction Period.** Where any correction or replacement of any Defective part of the Work or Tunnel Facility Project, including any part of the Work or Tunnel Facility Project that ceases to be used in commercial operations because of the Defective part of the Work or Tunnel Facility Project, including in respect of any damage or loss arising in respect of such correction or replacement, is carried out under this Section 9.8, then the Warranty Period will:

1. recommence at the beginning of the Warranty Period under Section 9.8(a) respecting the part of the Work or Tunnel Facility Project that was corrected or replaced, commencing on the date that such corrected or replaced part re-enters commercial operation; and
(2) respecting the part of the Work or Tunnel Facility Project that ceases to be used in commercial operations because of the Defective part of the Work or Tunnel Facility Project, be suspended as at the date that such Work or Tunnel Facility Project were taken out of commercial operation and will recommence on the date that such Work or Tunnel Facility Project re-enter commercial operation.

9.9 Acceptance of Defective Part of Tunnel Facility Project

If any part of the Work or the Tunnel Facility Project becomes or is determined to be Defective or fails because of any defect before the expiration of the relevant Warranty Period (as that period may be extended under Section 9.8(d)), OPG may deliver a Notice to the Contractor directing the Contractor not to correct or replace the Defective part of the Work or the Tunnel Facility Project in whole or in part. The Contractor will pay all of OPG’s costs respecting its evaluation of, and determination respecting, such Defective part of the Work and the Tunnel Facility Project (including all of OPG’s fees and charges of engineers, architects, accountants, lawyers (on a solicitor and his own client basis) and other professionals and all court, arbitration and other dispute mediation or resolution costs and charges). To the extent OPG accepts any such Defective part of the Work or the Tunnel Facility Project before OPG makes the final payment under Section 7.12, the Parties will reduce the Contract Price under an Amendment made in accordance with Section 5 to reflect an equitable reduction in the Contract Price for the Defective part of the Work or the Tunnel Facility Project. To the extent OPG accepts any such Defective part of the Work or Tunnel Facility Project after OPG makes the final payment under Section 7.12, the Contractor will pay OPG an agreed amount that reflects an equitable reduction in the Contract Price for the Defective part of the Work.

9.10 Warranty Work

The Contractor will perform in a timely manner all the warranty Work set out in this Agreement. In performing such Work at the Site, the Contractor will comply with all applicable terms of this Agreement respecting the performance of Work at the Site and will endeavour to minimize interference with, and impact on, OPG’s operations.

SECTION 10. DEFAULT

10.1 Events of Default

Each of the following events and circumstances constitutes an event of default by the Contractor under this Agreement:

(a) the Contractor or any Person providing a parental indemnity to OPG in accordance with Section 4.1(e) has been dissolved or has had a resolution passed for its winding-up or liquidation, other than in respect of an amalgamation, merger or consolidation;

(b) the Contractor or any Person providing a parental indemnity to OPG in accordance with Section 4.1(e) has made a general assignment, arrangement, composition or proposal with, or for the benefit of, its creditors;
(c) the Contractor or any Person providing a parental indemnity to OPG in accordance with Section 4.1(e) ceases to be, or admits that it is no longer, able to satisfy its obligations as they become due;

(d) the Contractor or any Person providing a parental indemnity to OPG in accordance with Section 4.1(e) has instituted, or has had instituted against it, a proceeding seeking a judgment of insolvency or bankruptcy or any other relief under any bankruptcy or insolvency law or similar Applicable Laws affecting creditor’s rights, or a petition is presented for its winding-up or liquidation and, in the case of any such proceeding or petition instituted or presented against it, such proceeding or petition:

(1) is instituted by or consented to by the Contractor or such Person providing a parental indemnity in accordance with Section 4.1(e);

(2) results in a judgment of insolvency or bankruptcy, the entry of an order for relief or the making of an order for its winding-up or liquidation and any such judgment or order has not been stayed pending an appeal; or

(3) if instituted against the Contractor or such Person providing a parental indemnity in accordance with Section 4.1(e) is not stayed pending an appeal and dismissed, discharged, stayed or restrained, in each case within 30 days of the institution or presentation thereof;

(e) the Contractor or any Person providing a parental indemnity in accordance with Section 4.1(e) has filed a petition, answer or consent seeking reorganization, readjustment, arrangement, composition or similar relief under any Applicable Law;

(f) the Contractor or any Person providing a parental indemnity in accordance with Section 4.1(e) has consented or becomes subject to the appointment of a receiver, liquidator or trustee or assignee in bankruptcy in respect of all or a substantial part of its assets and in the case that any such process, if instituted against the Contractor or such Person providing a parental indemnity in accordance with Section 4.1(e), as the case may be, has been instituted or presented against the Contractor or such Person providing a parental indemnity in accordance with Section 4.1(e), as the case may be, any such process has not been stayed pending an appeal and dismissed, discharged, stayed or restrained within 30 days thereafter;

(g) the Contractor or any Person providing a parental indemnity in accordance with Section 4.1(e) had a secured party take possession of all or a substantial part of its assets;

(h) the Contractor or any Person providing a parental indemnity in accordance with Section 4.1(e) has a distress, execution, attachment, or sequestration enforced or sued on or against all or a substantial part of its assets;
(i) the Contractor breaches any of its obligations (including any representations, warranties, guaranties and indemnities) under this Agreement, or under any document delivered under this Agreement, and fails to remedy the breach to the satisfaction of OPG within seven Business Days following receipt of Notice from OPG specifying the breach, or if the breach cannot be cured within such seven Business Day period, after such longer period of time as is reasonably required to cure the breach (but no longer than 60 days in any circumstances), so long as the Contractor diligently and constantly endeavours to cure the breach during such extended period provided that such cure period shall not apply to defaults described in Sections 10.1(j) to 10.1(p);

(j) the Contractor breaches or contravenes any Applicable Law in connection with this Agreement and (i) fails to provide a plan within seven Business Days following receipt of Notice from OPG specifying the breach or contravention, to remedy the breach or contravention which plan is satisfactory to OPG, or (ii) fails to comply with such plan; provided that the Contractor shall not be in default if the Contractor provides evidence to OPG (which is satisfactory to OPG) that such breach or contravention is not material;

(k) the Contractor’s conflict of interest declaration appended as Appendix 2.18 is or becomes incorrect, inaccurate or incomplete; or if measures cannot be instituted to address to OPG’s satisfaction a conflict which resulted from a change in circumstances as described in Section 2.18;

(l) the Contractor fails to obtain and maintain the maintenance bond, or the Performance LC(s) for this Agreement as required under Section 4.1;

(m) the Contractor fails to obtain and maintain the insurance required pursuant to Section 4.2;

(n) the Contractor, or any Subcontractor, or any Person providing a parental indemnity to OPG in accordance with Section 4.1(e), any of their shareholders, directors, officers, partners, members, representatives, agents or any of the Contractor’s Personnel gives or offers to give (directly or indirectly) to any Person, a bribe, gift, gratuity, commission or other thing of note, as an inducement or reward;

(1) for doing or forbearing to do any action in relation to this Agreement; or

(2) for showing favour or disfavour to any Person in relation to this Agreement;

(o) the Contractor assigns or attempts to assign this Agreement, in whole or in part, except in a manner expressly permitted in Section 14.1; or

(p) the Contractor fails to achieve Substantial Completion within 365 days of the date for Substantial Completion in the Contract Schedule.
10.2 Notice

OPG may terminate this Agreement immediately and without any cost to OPG by delivering a Notice to the Contractor on the occurrence of any event of default set out in Section 10.1.

10.3 OPG’s Recourse

If OPG is entitled to terminate this Agreement under Section 10.2, OPG may, in addition to its rights under Section 10.2 and without terminating this Agreement:

(a) eject and exclude from the Site the Contractor, any Subcontractor and any of the Contractor’s Personnel and prohibit the Contractor from continuing the Work;

(b) entirely finish the Work, in whole or in part, by whatever means OPG deems appropriate under the circumstances (and the Contractor, at no additional charge to OPG, will promptly, and in any event within three Business Days, provide OPG with all such records and work in progress that are not located on the Site and that are requested by OPG in a Notice);

(c) take possession of all or part of the Site, any work in progress, drawings, designs, Goods, Contractor’s construction equipment, tools, fuel and temporary structures and facilities, including for offices, lunchrooms, canteens, sanitation, showers, change rooms, accommodations, shops, warehouses and garbage disposal, at the Site (and at no additional charge for the retention and use thereof) (and the Contractor, at no additional charge to OPG, will cooperate to ensure the orderly transition of the foregoing);

(d) assume any and all subcontracts with Subcontractors;

(e) enforce any indemnity, performance bond, payment bond, maintenance bond, letter of credit, guarantee or other security provided by the Contractor, a Subcontractor or any other Person with respect to the applicable Work (although, if the terms of any such document permit earlier enforcement under any such document, OPG may enforce such rights in accordance with the terms of such other document);

(f) incorporate or use in the Tunnel Facility Project any or all Goods stored at the Site or for which OPG has paid the Contractor but which are stored elsewhere;

(g) withhold, without interest, all payments, in whole or in part, to the Contractor under any agreement between OPG and the Contractor until the Contractor’s liability to OPG is determined; and

(h) terminate the license of the TBM and the TBM Accessories granted by OPG to the Contractor.
10.4 Deemed Termination

If at any time after OPG terminates this Agreement under Section 10.2 or exercises its rights under Section 10.3, or both, it is determined for any reason that an event of default had not occurred or the default was otherwise excusable, the rights and obligations of the Parties will be the same as if the termination of this Agreement by OPG had occurred under Section 13.2.

10.5 Contractor’s Liability

If OPG terminates this Agreement under Section 10.2 or exercises its rights under Section 10.3, the Contractor will be liable to OPG for:

(a) all costs in excess of the Contract Price incurred by OPG to finish entirely the Work and the Tunnel Facility Project, including external and internal costs (including costs of additional engineering, management and administration);

(b) all costs of correcting Defective parts, if any, in the Work or Tunnel Facility Project, calculated in accordance with Section 9.8(c); and

(c) all other Losses suffered or incurred by OPG in respect of any event of default arising in respect of Section 10.1.

OPG may set off such amount, in whole or in part, as OPG determines is owing by the Contractor to OPG under this Section 10.5, against any amount otherwise owing by OPG to the Contractor.

10.6 Other Rights and Remedies

Any action by OPG under this Section 10 shall be without prejudice to OPG’s other rights or remedies under any guarantee, indemnity, bond or security held by OPG for performance of the Work by the Contractor.

10.7 OPG’s Liability

Notwithstanding any term in this Agreement, the Contractor may not make any claim against OPG for breach of this Agreement by OPG unless, the Contractor, within 10 Business Days after the Contractor discovered (as such term is defined in Section 5 of the Limitations Act (Ontario)) such breach by OPG of its obligations under this Agreement, gives Notice to OPG in the form attached as Appendix 10.7 describing the breach and the anticipated claim for the breach. The Contractor will be estopped from making any claim against OPG unless it provides this Notice in the time period required by this Section 10.7. Notwithstanding any term in this Agreement, OPG’s maximum liability for any claim for breach of this Agreement by OPG, other than failure to pay any part of the Contract Price otherwise due to the Contractor, will not exceed the Contract Price.

10.8 Limitation of Liability

Notwithstanding any term in this Agreement (other than Section 10.9), the liability of Contractor respecting all claims arising in respect of this Agreement will not exceed the greater of:
(a) an amount equal to the Contract Price; and
(b) the amount of insurance recoverable under this Agreement.

10.9 Exceptions

The limitations of liability set out in Section 10.8 will not apply, however, to:

(a) the Contractor’s obligations under Sections 2.4(f), 2.5(f), 2.15(f), 2.16(e), 8.1, 8.3, 9.1(e), 9.7, 9.8 and 10.5; and
(b) Losses suffered or incurred by a member of the OPG Group or any claims, demands, actions, suits or proceedings for Losses made against any member of the OPG Group by any Person, to the extent arising in respect of:

(1) the deliberate or willful breach of this Agreement by the Contractor; or
(2) liability for contribution or indemnity for injury or damage to third parties arising in respect of the Contractor’s negligence.

Except as set out in Sections 8.1 and 8.3 (including, for greater certainty, in the event of default by the Contractor hereunder, the payments under Sections 8.1 and 8.3 that would have been payable but for the exercise by OPG of its rights on default (using for this purpose the actual date of substantial completion of the work that was to be performed by the Contractor under this Agreement)), and except where recoverable under insurance or in respect of Losses suffered or incurred by a member of the OPG Group or any claims, demands, actions, suits or proceedings for Losses made against any member of the OPG Group by any Person to the extent arising in respect of the deliberate or willful breach of this Agreement by the Contractor, neither Party will be liable to the other Party for consequential liabilities, damages, losses, costs or expenses.

SECTION 11. DISPUTE RESOLUTION

11.1 Dispute Review Board

(a) Establishment. Promptly following the Start Date within the time period set out in Section 11.2(d), the Parties will co-operate in the execution of the agreement attached as Appendix 11.1(a) (the “Dispute Review Board Agreement”) establishing the Niagara Tunnel Project Dispute Review Board (the “Dispute Review Board”). The purpose of the Dispute Review Board is to assist in the resolution of any and all disputes arising in respect of performance of this Agreement (individually, a “Dispute”) as contemplated below.

(b) Amicable Resolution of Disputes. The Parties will endeavour to resolve all Disputes by good faith negotiation. The Dispute Review Board process is not intended to substitute for the Parties’ mutual ongoing commitment to resolve all Disputes in good faith as amongst themselves.
(c) **Principles.** All matters of process, scheduling and conduct of the Dispute Review Board will be determined by the needs of the Project and exigencies of the Contract Schedule. All Disputes will be heard as expeditiously as possible, and in order to achieve this, the Dispute Review Board may make all inquiries necessary.

(d) **Referral of Disputes to Dispute Review Board.** Except as expressly stated herein, if the Parties are unable to resolve any Dispute (other than a Default Dispute), the Dispute will be referred to the Dispute Review Board. In the case of a Default Dispute, such Dispute may be referred to the Dispute Review Board or to arbitration in accordance with Section 11.5.

(e) **Recommendations.** The Dispute Review Board will provide fully reasoned, written recommendations to the Parties to assist in the resolution of Disputes (“Recommendations”). The fully reasoned, written Recommendations of the Dispute Review Board are not binding on any party, although it is expected that the Parties will place great weight on the Recommendations and use them as a basis for settling Disputes.

(f) **Condition Precedent to any Further Proceedings.** If the Recommendations relating to a Dispute are not satisfactory to a Party (the “Dissatisfied Party”), the Dissatisfied Party, not later than 10 Business Days after receipt of the written Recommendations, may deliver written Notice to the other Party of the Dissatisfied Party’s intention to commence an action regarding the unresolved Dispute in a court of competent jurisdiction. All unresolved Disputes will be held in abeyance until the earlier of (i) Substantial Completion; and (ii) termination of this Agreement, except to the extent that holding such Dispute in abeyance could prejudice, by operation of the provisions of the *Limitations Act, 2002* (Ontario), the right of the Dissatisfied Party to commence an action regarding the unresolved Dispute. In the event that holding a Dispute in abeyance could prejudice, by operation of the *Limitations Act, 2002* (Ontario), the right of the Dissatisfied Party to commence an action regarding the unresolved Dispute, the Dissatisfied Party may commence such action prior to the expiry of the applicable limitation period. It is a condition precedent to any court proceeding that the Recommendations of the Dispute Review Board be pleaded in, referred to and attached as a schedule to the originating process. Either Party may plead or rely on this Agreement as evidence of the Parties’ consent to an order staying any and all proceedings pending formal annexation of the applicable Recommendations. If neither Party delivers written Notice to the other Party within 10 Business Days after receipt of written Recommendations from the Dispute Review Board of the Party’s intention to commence an action regarding the unresolved Dispute in a court of competent jurisdiction, the Parties will be deemed to have accepted the Recommendations of the Dispute Review Board, the Recommendations will be binding on the Parties, and the Parties will be estopped from commencing court proceedings regarding the unresolved Dispute.
11.2 Constitution of the Dispute Review Board

(a) Submission of Disclosure Statements. Before the Parties approve any member of the Dispute Review Board, each Party will cause the proposed member to deliver to the Parties a comprehensive disclosure statement. The Parties will ensure that each disclosure statement includes a resume of experience, together with a declaration describing all past, present and anticipated or planned future relationships to the Tunnel Facility Project and with each of OPG, the Contractor and each Subcontractor. Disclosure of relationships must include all recent, professional or personal, relationships with all key individuals of OPG, the Contractor and each Subcontractor.

(b) Initial Selection of Members. Nomination and approval of the first two members of the Dispute Review Board will occur as follows:

(1) OPG on the one hand and the Contractor on the other hand will each nominate a proposed board member and convey Notice of its nominee’s name and disclosure statement to the other (being OPG or the Contractor, as the case may be) within thirty days after the Start Date.

(2) by providing written Notice, either side may reject the other side’s nominee, without expressing a reason for the rejection, twice, and thereafter, if a side wishes to reject any further nominees, that side must provide reasonable written reasons or, alternatively, that side may accept a previously rejected nominee;

(3) any nominee who is not rejected in writing by the other side within seven days of receiving Notice of the nominee’s name and disclosure statement will be deemed to have been approved by the other side;

(4) if a nominee is rejected, the nominating side will make another nomination within seven days of receipt of the written Notice of rejection and the process will be repeated until two mutually acceptable nominees are approved;

(5) upon approval of two members of the Dispute Review Board, such first two members will choose a third member (who will be the chairperson) according to the following:

(A) the two members of the Dispute Review Board will prepare a single list of five possible names of candidates not previously rejected and corresponding disclosure statements which the two members will submit in writing simultaneously to the Parties;

(B) each Party can reject up to two people on this list, and each must return its list with the names of these people struck out, within seven days of receipt of the list of five names and corresponding disclosure statements. Failure of a Party to provide strike-outs
within this time shall constitute deemed acceptance of the entire list;

(C) the first two members will then compare the lists and select, in their sole and absolute discretion, any non-rejected person as the third member of the Dispute Review Board; and

(D) upon selection, the first two members will then promptly disclose their choice to the Parties.

(c) **Members Qualifications.** Only individuals experienced with the type of construction involved in respect of the Tunnel Facility Project, and with the interpretation of agreements similar to this Agreement, may be nominated to the Dispute Review Board. In selecting nominees for the Dispute Review Board, the Parties will only nominate individuals with a demonstrated ability to provide leadership for the Dispute Review Board’s activities. The other mandatory criteria for selecting members of the Dispute Review Board are set out below. These are enduring criteria that apply at all times to all members and nominees of the Dispute Review Board:

1. **No Current Financial Interests.** Neither Party will nominate any individual, or permit any member of the Dispute Review Board to remain a member, if that individual or member has a financial interest in OPG, the Contractor or any Subcontractor, or otherwise has any financial interest in the Tunnel Facility Project or this Agreement.

2. **No Prior Financial Interest.** Neither Party will nominate any individual, or permit any member of the Dispute Review Board to remain a member, who, except for fee-based consulting services on other projects unrelated to the Work and the Tunnel Facility Project, was previously employed by, or had financial ties to, OPG, the Contractor, or any Subcontractor.

3. **No Close Relationships.** Neither Party will nominate any individual, or permit any member of the Dispute Review Board to remain a member, who has a then current or recent, close, professional or personal, relationship with any key individual of OPG, the Contractor, or any Subcontractor.

4. **No Previous Involvement in Work.** Neither Party will nominate any individual, or permit any member of the Dispute Review Board to remain a member, who has had a substantial, relevant prior involvement in the Tunnel Facility Project of a nature which could reasonably be expected to compromise the individual’s or the member’s, as the case may be, ability to participate impartially in the activities of the Dispute Review Board.

5. **No Employment.** Neither Party will employ, or offer or commit to employ or otherwise engage, a Dispute Review Board member during the member’s tenure.
(d) **Agreement with Members.** Each of the Parties and all three members of the Dispute Review Board will execute the Dispute Review Board Agreement in the form set out in Appendix 11.1(a) within four weeks after the selection and approval of the third member of the Dispute Review Board.

(e) **Replacement Members.** The Parties may agree to terminate the tenure of any member of the Dispute Review Board at any time in writing. Neither OPG nor the Contractor may unilaterally terminate the tenure of any Dispute Review Board member. The Dispute Review Board Agreement will survive the termination, resignation, death or incapacity of any member. If the tenure of any Dispute Review Board member is terminated or if any such member otherwise ceases to participate on the Dispute Review Board, the two remaining members of the Dispute Review Board will use the process set out in Section 11.2(b)(5) to select a new third member, and the new third member will sign a new Dispute Review Board Agreement with the other two members and with the Parties. If two or three members are terminated, the procedure in Sections 11.2(b) and 11.2(c) will apply until those positions are filled.

11.3 **Operation**

(a) **Beginning and Completion.** The Dispute Review Board will remain empanelled and active throughout the duration of the Tunnel Facility Project, irrespective of the fact its actual composition may change from time to time.

(b) **Individual Communication.** No individual member of the Dispute Review Board will have any private communication with either Party.

(c) **General Procedure.** Dispute Review Board operating procedures will be formulated by the Dispute Review Board as a task under the Dispute Review Board Agreement. It is anticipated that during its first meeting at the Site, the Dispute Review Board will establish procedures for the conduct of its routine meetings, Site visits, and hearings of Disputes. The Parties direct the Dispute Review Board to adapt such procedures as required, in its unfettered discretion, to best achieve the objects of the Dispute Review Board. The Parties acknowledge that the Dispute Review Board may initiate new procedures or modify existing procedures as it deems appropriate or necessary to best achieve the object of the Dispute Review Board. The Parties undertake and agree to comply with all such procedures.

(d) **Agreement, Reports and Information.** The Parties will provide a conformed set of plans and specifications to each Dispute Review Board member. The members will thereafter remain informed of construction activity and other developments by means of timely transmittal of relevant information prepared by OPG and the Contractor in the normal course of construction, including through periodic progress reports and minutes of progress meetings.
(e) **Progress Meetings.** In addition to its other duties, the Dispute Review Board will meet at regular intervals, no less frequently than quarterly, and at times of significant construction events. The frequency and scheduling of these meetings will be as agreed among the Parties and the Dispute Review Board, depending upon the progress of the Work. In the case of failure to agree, the Dispute Review Board will schedule the meetings. Each meeting will consist of an informal roundtable discussion followed by an optional field observation of the Tunnel Facility Project. The informal roundtable discussion will be attended by key personnel from OPG and the Contractor. The agenda for each meeting will include no fewer than the following items:

1. Approval of minutes of previous meeting (to be kept by OPG, and circulated for approval within seven days of each meeting, or less if necessary);
2. Work performed since the last meeting;
4. Anticipated or potential problems and proposed solutions;
5. Perspectives on potential Disputes, claims and other controversies;
6. Status of past Disputes, claims and other controversies;
7. New business; and
8. Set date, time and place of next meeting and Site visit.

### 11.4 Review of Disputes

(a) **General.** The Parties will cooperate to ensure that the Dispute Review Board is able to consider Disputes promptly.

(b) **Prerequisites to Review.** Provided that it has not been expressly excluded from referral herein, a Dispute (other than a Default Dispute, which Dispute may be referred to the Dispute Review Board or to arbitration in accordance with Section 11.5) will be referred to the Dispute Review Board when:

1. Either Party believes that good faith bilateral negotiations have not and are not likely to succeed or have reached an impasse; or
2. If this Agreement provides for a prior decision by OPG’s Representative or a professional, and such decision has been issued and is unacceptable to a Party.

(c) **Disputes.** Provided that it has not been expressly excluded from referral herein, either Party may refer a Dispute to the Dispute Review Board. Requests for
Dispute Review Board resolution must be submitted in writing to the chairperson of the Dispute Review Board and must state the Dispute, with particularity, arising in respect of this Agreement, including a sworn statement that negotiations have been attempted and exhausted or otherwise failed (the “Dispute Request”). The Party referring the Dispute to the Dispute Review Board will simultaneously submit a copy of the Dispute Request in compliance with this Section 11.4(c) to the other Party. After conferring with both Parties, the Dispute Review Board will establish a hearing procedure that is as summary, efficient, and inexpensive as possible in the circumstances and in accordance with the principles set out above.

(d) **Substantial and Complex Disputes.** If and only if the Dispute cannot be resolved summarily by exercise of the Dispute Review Board’s inquisitorial powers, and (i) the Dispute Review Board considers it to be necessary, or (ii) the Parties make a joint request, the Dispute will be heard as follows:

1. Concise written statements will be prepared by both Parties, together with a binder of relevant supporting documents, indexed, paginated in one continuous sequence throughout the binder, each document separated from each other document by sequentially numbered index tabs corresponding to the index.

2. The Party initiating the Dispute will serve its statement (the “**Applicant’s Statement**”) on the other Party and file three copies with the chairperson of the Dispute Review Board within the time set by the Dispute Review Board. The Applicant will set out a proposed method and schedule for the hearing in its Applicant’s Statement.

3. The respondent’s statement (the “**Respondent’s Statement**”), prepared in identical form, will be similarly served and filed within the time set by the Dispute Review Board. The respondent will set out a proposed method and schedule for the hearing in the Respondent’s Statement.

4. The Dispute Review Board may, by written notice to the Parties, require either or both of the Parties to support their respective statements with documents, affidavits, declarations, tests, samples, photographs, videos, reports or other material, in the Dispute Review Board’s sole and absolute discretion, and at any time and from time to time.

5. The Dispute Review Board will acknowledge in writing to the Parties that the Dispute is perfected in accordance with this section when all of (1), (2), (3) and (4) above are complied with and shall, at the same time, advise the Parties as to the method and schedule for the hearing having regard to the Parties’ positions as recorded in their statements.
(e) **Board to Visit Site.** In the case of a Dispute referred to the Dispute Review Board, either Party to the Dispute or the Dispute Review Board itself may request that a Site visit be undertaken before, or as part of, any hearing.

(f) **Hearing.** The place of the hearing will be at the Site at a time and on a date stipulated by the Dispute Review Board in consultation with the Parties. If circumstances require, the Dispute Review Board may, with the prior consent of the Parties, adjourn all or a portion of the hearing of the Dispute to any other location or time.

(1) **Proceedings in Confidence.** The proceedings of the Dispute Review Board hearing will be conducted and maintained as far as possible in absolute privacy, privilege and confidence.

(2) **Representation.** Each Party has the right, but not the obligation, to be represented by counsel at any hearing or any portion of any hearing, at its own expense.

(3) **No Transcripts Required.** No transcript is required to be kept of any testimony before the Dispute Review Board, but, if such testimony is taken and transcribed, a copy must be provided to the other Party once received.

(4) **Hearing Procedure.** The order of proof, the fact and extent of oral evidence (whether under oath or not), examinations and cross-examinations (whether under oath or not), the quality of proof, the burden of proof, argument both written and oral, and all matters of form, procedure, and process relating to the hearing before the Dispute Review Board are within the absolute discretion of the Dispute Review Board.

(g) **Inquiry by Board.** The Dispute Review Board is expressly authorised by the Parties to take all accounts, make all inquiries, give all directions and do all things necessary to reach their Recommendations. The Parties agree to satisfy, in good faith, and as soon as practicably possible, any inquiries made by the Dispute Review Board, including where appropriate, the production of any documents, affidavits, declarations, tests, samples, photographs, videos, reports or other material, which inquires are made in their sole and absolute discretion, at any time and from time to time.

(h) **Deliberations.** The chairperson of the Dispute Review Board will declare the hearing closed at the close of argument and thereafter the Dispute Review Board will have, in aggregate, no more than two weeks for deliberation and delivery of its Recommendations.

(i) **Recommendations.** The Dispute Review Board’s Recommendation for the resolution of the Dispute will be transmitted to both Parties simultaneously at the end of the period of deliberation. In a difficult or complex case, this time period may be extended at any time and from time to time by agreement of the Parties.
The Dispute Review Board will use best efforts to reach a unanimous Recommendation on every Dispute, however, if unanimity is not reached, individual Recommendations are permissible.

(j) **Clarification and Reconsideration**: If either Party feels that the Recommendations require clarification or reconsideration, that party may so request, in writing, specifying with all possible particularity that Party’s reasons, and the Dispute Review Board may or may not, in its sole and absolute discretion, elect to clarify, re-deliberate or re-open the hearing for the purpose set out in the Party’s request, and if the hearing is re-opened, the requirements set out in this section apply once again.

11.5 **Arbitration**

If a Dispute arises as to whether an event of default has occurred under Section 10.1 of the Agreement (a “**Default Dispute**”), either Party to the Default Dispute may elect to have such Dispute resolved by arbitration under the Arbitration Act, 1991 (Ontario) (the “Arbitration Act”). This election shall be made either prior to or within two Business Days after the delivery of a Dispute Request under Section 11.4(c) of this Agreement by delivery to the Other Party of a written Notice to Arbitrate. If either Party elects to have a Default Dispute resolved by arbitration, the Parties shall have no further recourse to the Dispute Review Board in respect of this Default Dispute, and the Dispute Review Board shall have no jurisdiction to consider this Default Dispute. The sole issue to be determined by the arbitrator in the arbitration shall be whether an event of default under Section 10.1 has occurred. The arbitrator shall have no jurisdiction to award any remedy arising from such determination. The following provisions shall apply to the arbitration:

(a) the arbitration shall be determined by a single arbitrator who is independent of any Party and who shall be a lawyer experienced in and knowledgeable about construction contracts;

(b) in the event that the Parties cannot agree to the appointment of an arbitrator within 5 Business Days prior to the commencement of the arbitration, either Party may apply to the Superior Court of Justice of Ontario for the appointment of an arbitrator with the qualifications set out above;

(c) all matters relating to the arbitration shall be kept confidential to the full extent permitted by law until the date of the release of the decision of the arbitrator, and no individual shall be appointed as an arbitrator unless he or she agrees in writing to be bound by this dispute resolution provision;

(d) the application of Section 7(2) of the Arbitration Act is expressly excluded;

(e) each Party shall provide to the other Party within 15 days prior to the commencement of the arbitration copies of the relevant, non-privileged documents in the Party’s possession, power or control;
each Party to the arbitration shall be permitted to conduct an examination of a representative of the other Party, which examination shall last for no longer than one day;

the hearing shall take place within 60 days after the commencement of the arbitration;

the arbitrator shall render his or her decision within 15 days after the conclusion of the hearing;

in all other respects, the arbitration process shall be determined by agreement of the Parties or by the arbitrator;

the arbitrator will apply the laws of the province of Ontario and Canada to decide the Default Dispute; and

the place of arbitration will be Toronto, Ontario and the arbitration will be conducted in the English language.

Subject to Section 44 of the Arbitration Act, the decision of the arbitrator in an arbitration under this section will be final and binding on the Parties and the Parties will have no right of appeal on any ground, including, for greater certainty, any appeal on a question of law, a question of fact, or a question of mixed fact and law. The arbitrator’s decision with respect to the Default Dispute shall be pleaded, referred to and scheduled to the originating process in any subsequent proceedings brought in a court of competent jurisdiction for a remedy resulting from that decision.

SECTION 12. ESCROW INFORMATION

12.1 Delivery of Escrow Information

The Contractor shall submit to OPG, within three (3) Business Days after the signing of this Agreement, in a sealed container, one copy of all documentary information respecting the Contractor’s preparation of the Contract Price (collectively, the “Escrow Information”). Notwithstanding any term in this Agreement, nothing in the Escrow Information will amend, restate or terminate this Agreement in whole or in part.

12.2 Contractor’s Representation

The Contractor represents and warrants to OPG that the Escrow Information constitutes all the documents and other information used by the Contractor in preparing and negotiating the Contract Price. The Parties may use any of the Escrow Information to assist in the settlement of Disputes. No other information of the Contractor used by the Contractor in preparing and negotiating the Contract Price will be considered in resolving such Disputes.
12.3 Initial Review by OPG

Shortly after delivery pursuant to Section 12.1, the Escrow Information will be unsealed, examined, organized, and inventoried by representatives of OPG, together with members of the Contractor’s staff who are knowledgeable in how the Contractor’s proposal was prepared.

The examination under this Section 12.3 will be for the purposes of ensuring that the Escrow Information is authentic, legible, and complete. It will not include review of, and will not constitute approval of, proposed construction methods, estimating assumptions, or interpretations of this Agreement. If the Contractor fails to include in the Escrow Information any documentary information that the Contractor was required to include pursuant to Section 12.1, then such missing documentary information will be determined by OPG, acting reasonably. The examination under this Section 12.3 will not alter any conditions or terms of this Agreement.

12.4 Ownership

The Escrow Information is the property of the Contractor. The Escrow Information is nevertheless subject only to joint review by the Parties and the Dispute Review Board as provided in this Agreement. OPG stipulates and expressly acknowledges that the Escrow Information constitutes trade secrets. Neither Party will review the Escrow Information unless the other Party is present during such review.

12.5 Purpose

Both parties hereby consent that the Escrow Information may be used in the negotiation of adjustments for changes to the Work and in the settlement of Disputes.

12.6 Storage

The Escrow Information will be placed in escrow, following initial review by OPG pursuant to Section 12.3, for the life of this Agreement, with a third party and held at a secured location with access only provided as permitted by Section 12.7.

12.7 Examination After Signing

The Escrow Information may be examined by OPG, the Contractor and the Dispute Review Board, at any time deemed necessary after the signing of this Agreement to assist in the settlement of Disputes. Neither Party will review the Escrow Information unless the other Party is present during such review.

Examination of the Escrow Information is subject to the following conditions:

(a) As trade secrets, the Escrow Information is proprietary and confidential.

(b) All documents related to the issue being reviewed shall be inspected.
(c) OPG and the Contractor shall each designate, in writing to the other party a minimum of ten calendar days prior to examination, representatives who are authorized to examine the Escrow Information.

(d) Members of the Dispute Review Board may examine the Escrow Information as deemed necessary by the Dispute Review Board.

(e) Access to the Escrow Information will take place only with the knowledge of the Contractor’s representatives and the opportunity to be present at the time of examination.

(f) No other Person shall have access to the Escrow Information.

SECTION 13.  SUSPENSION OF WORK AND TERMINATION

13.1 Suspension of Work

OPG may at any time, and from time to time, for any reason without affecting the validity of this Agreement, suspend the performance of the Work in whole or in part for such period of time as OPG may notify the Contractor. Except to the extent any such suspension arises in respect of any default by the Contractor or any negligent or willful act or omission of the Contractor or a Subcontractor, OPG will pay the Contractor the reasonable extra direct damages suffered by the Contractor arising from the suspension. Except for such extra direct damages, notwithstanding any term in this Agreement, in no circumstances whatsoever will OPG be liable to the Contractor for consequential liabilities, damages, losses, costs or expenses suffered or incurred by the Contractor in any such suspension. Severance costs respecting the termination of any of the Contractor’s Personnel do not constitute direct damages. Before OPG pays the Contractor for such extra direct damages, the Contractor will provide to OPG such reasonable evidence of such damages as OPG may request. In addition, before making any payment, OPG may conduct an audit of such damages and the Contractor will provide OPG with all information reasonably requested by OPG in respect of such audit. Immediately following a Notice of resumption delivered by OPG to the Contractor, the Contractor will resume performing the Work in accordance with the schedule established by OPG.

13.2 Termination

OPG may from time to time, without cause and without affecting the validity of this Agreement, immediately terminate any unprovided Work, in whole or in part, by delivering a Notice to this effect to the Contractor. Upon receipt of such Notice, the Contractor will cease performing the designated portion of the Work which is the subject of termination, but will continue to perform all Work not subject to termination. Except to the extent any such termination arises in respect of any event of default by the Contractor, OPG will pay the Contractor:

(a) the amounts set out in this Agreement for all parts of the Work that have been entirely finished and delivered in accordance with the terms of this Agreement, and for which OPG has not made any payment;
(b) the amount of the Contractor’s costs determined in accordance with Section 7.7(b) incurred in providing the work in progress, not including the Work referred to in Section 13.2(a); and

(c) the reasonable extra direct damages suffered by the Contractor arising from the termination (such as the reasonable out-of-pocket costs of demobilization).

Except for such amounts referred to in Sections 13.2(a) and 13.2(b) and direct damages referred to in Section 13.2(c), notwithstanding any term in this Agreement, in no circumstances whatsoever will OPG be liable to the Contractor for consequential liabilities, damages, losses, costs or expenses, damages, loss of profit, economic loss, interest or any other damages or loss suffered or incurred by the Contractor in any such termination. Before OPG pays the Contractor for such amounts referred to in Sections 13.2(a) and 13.2(b) and direct damages referred to in Section 13.2(c), the Contractor will provide to OPG such reasonable evidence of such amounts and damages as OPG may request. In addition, before making any payment, OPG may conduct an audit of such amounts and damages and the Contractor will provide OPG with all information reasonably requested by OPG in respect of such audit. On payment for such amounts and damages, title to all the remainder of the Work (including documents, designs, drawings, specifications, plans, reports, information and other deliverables and data) that had not to date vested in OPG, will vest automatically in OPG.

SECTION 14. GENERAL

14.1 Assignment and Benefit

The Contractor may not assign this Agreement, in whole or in part, without the prior written consent of OPG except to a wholly-owned subsidiary of the Contractor provided that the Contractor is not released from its obligations under this Agreement and provided further that the Contractor provides prior Notice to OPG. In the event of an assignment by the Contractor of this Agreement, any reference to the Contractor under this Agreement shall include the assignee. This Agreement enures to the benefit of and binds the Parties and their respective successors and permitted assigns. OPG may from time to time transfer, assign, sell, lease or otherwise dispose of certain assets relating to one or more electricity generating stations or other business units of OPG (each station or other unit being a “Business Unit”). Notwithstanding any term in this Agreement, OPG may, without the consent of the Contractor, assign this Agreement, in whole or in part, and sublicence, assign or transfer OPG’s rights respecting the Retained Intellectual Property, as that term is defined in Section 2.16(c), in whole or in part, to any owner, operator, lessee or any other successor in interest of a Business Unit (an “Assignee”). OPG may disclose to an Assignee or a proposed Assignee any information and documentation respecting this Agreement. The Assignee may use the Retained Intellectual Property, in accordance with the rights sublicensed, assigned or transferred by OPG. In addition, OPG may divide OPG’s rights under this Agreement with any Assignee in such a manner as to permit both OPG and the Assignee to realize the full rights that OPG is entitled to under this Agreement. Effective immediately upon any such assignment or transfer by OPG and assumption, in whole or in part, by an Assignee of any of OPG’s obligations respecting such assignment or transfer, OPG will be automatically released and forever discharged from the obligations to the extent that they are assumed. The Contractor will from time to time and promptly upon request, sign and deliver all
further documents and take all further action reasonably necessary or appropriate to give effect to the terms and intent of this Section 4.1.

14.2 Amendments

OPG’s Representative, or an officer senior to OPG’s Representative, are the only individuals authorized to execute any Amendment on behalf of OPG. Aside from those individuals, no other Person has any authority to make any agreement, undertaking, representation, warranty, guarantee, release or waiver on behalf of OPG in respect of this Agreement. Except as expressly provided in this Agreement, no amendment (including an Amendment), restatement or termination of this Agreement in whole or in part is binding unless it is in writing and signed by each Party. Accordingly, this Agreement will not be amended by any Application for Payment, invoice or other document (even where such Application for Payment, invoice or other document purports, directly or indirectly, to be paramount to any term of this Agreement), unless such Application for Payment, invoice or other document is signed by both Parties.

14.3 Discretion Granted

Wherever OPG is granted sole and absolute discretion or the power to refuse a change in this Agreement, the exercise of such discretion or power will not be subject to the dispute resolution process under Section 11 or any other claim by the Contractor.

14.4 Notice

Except as otherwise provided in this Agreement, such as in Section 10.2, every Notice required or permitted under this Agreement must be in writing and may be delivered in person, by courier or by fax to the applicable Party, as follows:

If to OPG, Ontario Power Generation Inc.  if to the Contractor, Strabag AG
700 University Avenue, H  Donau-City-Str. 9
Toronto, Ontario, M5G 1X6  1220 Wien (Vienna)
Attention: Emad Elsayed  Austria
Fax: 416-592-6552  Attention: Ernst Gschnitzer

with a copy to:
Hatch Associates
2800 Speakman Drive
Mississauga, Ontario, L5K 2R7

Attention: Harry Charalambu
Fax: 416-905-855-2607

or to any other address, fax number or individual that a Party designates by Notice. Any Notice under this Agreement, if delivered personally or by courier will be deemed to have been given when actually received, if delivered by fax before 3:00 p.m. on a Business Day will be deemed to
have been delivered on that Business Day and if delivered by fax after 3:00 p.m. on a Business Day or on a day which is not a Business Day will be deemed to be delivered on the next Business Day.

14.5 Currency

Unless otherwise specified, all amounts to be paid or calculated under this Agreement are to be paid or calculated in Canadian dollars.

14.6 Set Off

OPG may set off any amount owing to OPG from the Contractor from any amount otherwise due, owing, or payable by OPG to the Contractor.

14.7 Waivers

No waiver of any term of this Agreement is binding unless it is in writing and signed by all the Parties entitled to grant the waiver. No failure to exercise, and no delay in exercising, any right or remedy, under this Agreement will be deemed a waiver of that right or remedy. No waiver of any breach of any term of this Agreement will be deemed to be a waiver of any subsequent breach of that term.

14.8 Cumulative Remedies

OPG’s rights and remedies under this Agreement and under any security held by OPG for the Contractor’s performance under this Agreement are cumulative and are in addition to and not in substitution for any other rights and remedies available at law or in equity or otherwise. No single or partial exercise by a Party of any right or remedy precludes or otherwise affects the exercise of any other right or remedy to which that Party may be entitled.

14.9 Survival of Obligations

All representations, warranties, guarantees and indemnities made in, required by or given under this Agreement, as well as all continuing obligations under this Agreement, will survive final payment made under Section 7.12, Substantial Completion and acceptance of the Tunnel Facility Project and termination or expiry of this Agreement.

14.10 Relationship of Parties

Nothing in this Agreement will be construed as constituting either Party as the agent, partner, joint venturer or other representative of the other Party. The relationship between the Parties is that of a purchaser and an independent contractor. The Contractor’s Personnel are solely the employees of the Contractor and Subcontractors (and not OPG’s) for all purposes under this Agreement, including for all purposes under any Applicable Laws. Accordingly, none of the Contractor’s Personnel or Subcontractors is entitled to any benefits respecting any pension or other benefit plan, program or policy of OPG. The Contractor will pay all Taxes respecting each of the Contractor’s Personnel and each of the Subcontractors and OPG will have no responsibility for any such Taxes.
14.11 No Third Party Beneficiary

This Agreement is solely for the benefit of the Parties and, to the extent expressly and specifically made beneficiaries of this Agreement. In particular, OPG holds the rights of all third party beneficiaries under Sections 2.4(f)(4), 2.4(j), 2.5(f), 2.14(e), 2.14(j), 2.15(f), 2.16(e), 2.17(d) and 9.1(e) in trust for the benefit of such third party beneficiaries. Otherwise, no term of this Agreement will be deemed to confer upon other third parties any claim, remedy, reimbursement or other right. The Contractor represents and warrants to OPG that the Contractor is entering into this Agreement solely on its own behalf and not as agent for any other Person.

14.12 Acknowledgement as to Negotiation of this Agreement

Each Party acknowledges that all Parties have participated in the drafting of this Agreement. Accordingly, no term of this Agreement will be interpreted less favourably to any Party because that Party or its counsel was primarily responsible for the drafting of that term.

14.13 Choice of Language

The Parties confirm that it is their wish that this Agreement, as well as any other documents respecting this Agreement, including Notices, schedules and authorizations, have been and will be drawn up in the English language only. Les parties aux présentes confirment leur volonté que cette convention, de même que tous les documents, y compris tous avis, cédules et autorisations s’y rattachant, soient rédigés en langue anglaise seulement.

14.14 Counterparts

This Agreement and any Amendment, restatement or termination of this Agreement in whole or in part may be signed and delivered in any number of counterparts, each of which when signed and delivered is an original but all of which taken together constitute one and the same instrument. This Agreement and any Amendment, restatement or termination of this Agreement in whole or in part may be delivered by fax.

14.15 Freedom of Information

The Contractor expressly acknowledges that OPG is subject to the provisions of the Freedom of Information and Protection of Privacy Act, R.S.O. 1990, C.F.31, and any confidentiality covenants of OPG set out in this Agreement are granted expressly subject to any and all disclosure requirements that may exist or may in the future arise under the Freedom of Information and Protection of Privacy Act, as may be amended or replaced by time to time.
The Parties have duly executed this Agreement.

Appendix 1.1(b) - Amendment Form

AMENDMENT AGREEMENT NUMBER [1]

This Agreement is made as of [●], 200[●] between

ONTARIO POWER GENERATION INC., a corporation
existing under the laws of Ontario (“OPG”),

and

STRABAG AG, a corporation existing under the laws of Austria
(the “Contractor”).

RECITALS

A. OPG and the Contractor entered into a design/build agreement dated as of [■], 200[5]
(the “Original Agreement”).

B. OPG and the Contractor have agreed to amend the Original Agreement to [insert brief
description of amendment, 1-2 lines].

C. For value received, the Parties agree as follows.

Interpretation

Any defined term used in this Agreement that is not defined in this Agreement has the meaning
given to that term in the Original Agreement. In this Agreement, the following terms have the
respective meanings set out below.

● [Insert any definitions required in this Agreement.]

Change to Section [●] (Title of Section)

Section [●] of the Original Agreement is deleted in its entirety and replaced with the following. OR Section [●] of the Original Agreement is deleted in its entirety. OR The following Section is added as a new Section [●] to the Original Agreement.

Change to Section [●] (Title of Section)

Section [●] of the Original Agreement is deleted in its entirety and replaced with the following. OR Section [●] of the Original Agreement is deleted in its entirety. OR The following Section is added as a new Section [●] to the Original Agreement.

Original Agreement Remains in Full Force

Except for changes to the Original Agreement set out in this Agreement and any previous
Amendment, the Original Agreement remains in full force, unamended, including the provisions
relating to Contract Price and Contract Schedule. [Note: Insert any changes to Contract Price or Contract Schedule if relevant.]

The Parties have duly executed this Agreement.

Appendix 1.1(d) - Payment Related Documents

Certificate - Application for Payment

TO: Ontario Power Generation Inc. (“OPG”)

RE: Design/Build Agreement (the “Agreement”) between OPG and Strabag AG (the “Contractor”), dated as of [date] for the Niagara Tunnel Facility Project

I, [name], am the [title] of the Contractor and am authorized to deliver this Certificate on behalf of the Contractor. I hereby certify, for and on behalf of the Contractor, that:

(a) the coverages that the Contractor is obliged to maintain under Section 4.2 of the Agreement remain in full force;

(b) the Contractor has paid in a timely manner all amounts payable under the Workplace Safety and Insurance Act, 1997 (Ontario);

(c) the Contractor remains in compliance with all its other obligations under the Workplace Safety and Insurance Act, 1997 (Ontario);

(d) the Contractor has provided OPG with the Workplace Safety and Insurance Board registration number for each member of the Contractor’s Personnel performing Work at the Site for the period covered by the certificate; and

(e) [there are no known outstanding claims under the Agreement, except for those claims which have already been communicated to OPG in a timely manner in the form of Notice required by the Agreement and which are listed in the Appendix to this Certificate, including an estimate of the value of each such claim;] or

[there are outstanding claims which have not been communicated to OPG in the form of Notice required by this Agreement and each of these claims is described in the attached form of Notice required by this Agreement and is delivered to OPG in a timely manner, and there are no other known outstanding claims under the Agreement, except for those claims which have already been communicated to OPG in a timely manner in the form of Notice required by this Agreement and which are listed in the Appendix to this Certificate, including an estimate of the value of each such claim.]
Defined terms used in this Certificate that are not defined in this Certificate have the meanings given to those terms in the Agreement.

DATED: [date], 200[●].

STRABAG AG

Statutory Declaration - Application for Payment

C A N A D A  )  IN THE MATTER OF THE DESIGN/BUILD
   )  AGREEMENT BETWEEN ONTARIO
   )  POWER GENERATION INC. AND
   )  STRABAG AG (the “Contractor”)

PROVINCE OF ONTARIO  )  DATED AS OF [DATE] FOR
   )  THE NIAGARA TUNNEL FACILITY
   )  PROJECT (the “Agreement”)

I, [●], of the [City] of [●], Ontario, do solemnly declare that:

I am the [title] of Contractor and as such have personal knowledge of the facts set out in this solemn Declaration.

Defined terms used in this solemn Declaration but not defined in this solemn Declaration have the meanings given to those terms in the Agreement.

All payments due to Subcontractors; all wages and benefit payments due to any of the Contractor’s Personnel; and all contributions, premiums, allowances and remittances due to any Governmental Authority, pension fund, benefit plan or union fund in accordance with a collective agreement or Applicable Laws, have been paid in a timely manner on or before the date of the Application for Payment to which this solemn Declaration relates, subject to any withholdings or holdbacks required by Applicable Laws.

Title to the applicable part of the Project will pass to OPG in accordance with Section 7.4 of the Agreement no later than the date of OPG’s payment to which this solemn Declaration relates.

(a)  [there are no known outstanding claims under the Agreement, except for those claims which have already been communicated to OPG in a timely manner in the form of Notice required by the Agreement and which are listed in the Appendix to this solemn Declaration, including an estimate of the value of each such claim;] or

(b)  [there are outstanding claims which have not been communicated to OPG in the form of Notice required by this Agreement and each of these claims is described in the attached form of Notice required by this Agreement and is delivered to OPG in a timely manner, and there are no other known outstanding claims under the Agreement, except for those claims which have already been communicated to OPG in a timely manner in the form of Notice required by this Agreement and which are listed in the Appendix to this solemn Declaration, including an estimate of the value of each such claim.]
I make this solemn Declaration conscientiously believing it to be true and knowing it is of the same force as if made under oath.

DECLARED before me at the City of ■, in the County/Region of ■, this day of [●], 200[●].

A Commissioner, etc.                               Name

This Contract Price is to divert a GFA of 500 m$^3$/s (at the reference hydraulic head and the reference elevation of the energy grade line as defined in Appendix 1.1(aa), Flow Verification Test) of the flow of the Niagara River from an intake located under the International Niagara Control Works, to an outlet that will discharge into the existing canal system that feeds the existing Sir Adam Beck hydroelectric plants at Queenston, Ontario.
ALTERNATIVE 1 TO CONTRACT PRICE

As an alternative to the Constraint 3.1(c)(i) in Appendix 1.1(sss), Summary of Work, of the Design/Build Agreement, the Contractor offers the following credit to its Contract Price and change to the Substantial Completion Date if a single continuous closure of the PGS is permitted by OPG for Work associated with:

(a) connection of the outlet canal to the PGS canal; and

(b) for Work associated with demolition and disposal to off-site location(s) of the existing dewatering structure in the PGS canal should such Work be directed by OPG.

Credit to Contract Price: $375,000.00

Number of calendar days of single continuous closure of the PGS required to secure Credit to Contract Price: six (6) days.

Revised Substantial Completion Date proposed with single continuous closure of the PGS: October 6, 2009.

This offer of a reduction in the Contract Price and the associated schedule impacts shall remain in force for the duration of the Agreement and may be accepted by OPG at any time at its sole discretion.

ALTERNATIVE 2 TO CONTRACT PRICE

The Contract Price will be increased by the amount set out below for each previously agreed 6-hour closure period of PGS, subsequently confirmed with OPG within 2 to 5 days of agreed time of closure, that OPG fails to deliver to Contractor for Work associated with:

(a) connection of the outlet canal to the PGS canal; and

(b) for Work associated with demolition and disposal to off-site location(s) of the existing dewatering structure in the PGS canal, should such Work be directed by OPG,

provided that Proponent has complied with all requirements of the Summary of Work Constraints at 3.1(c) of Appendix 1.1(sss) of the Agreement, and with all other terms and conditions of the Agreement regarding such closure.

Increase in Contract Price per occurrence: $62,500.00.

OPTIONAL PRICE ADJUSTMENT

The following adjustment shall be made to the Contract Price in the event that OPG shall instruct the Contractor not to remove the temporary access roads constructed as part of the Work:

The Price Adjustment for the intake area access road is $0.0
The Price Adjustment for the outlet access road is $0.0

*The following all inclusive unit rates will be used to evaluate changed quantities above and below the baseline quantities in the GBR:*

**UNIT RATES FOR DRILLING AND GROUTING**

**Gallery grouting**

| Mobilization and demobilization (to and from gallery) of plant and equipment for drilling and grouting in gallery | Each campaign | 1,500.00 CAD |
| Drilling max. 51 mm dia., max length = 5,00m | per m | 33.00 CAD |
| Drilling max. 51 dia., length = 5,01-10,00m | per m | 39.00 CAD |
| Grout connection | per No. | 1,430.00 CAD |
| Grouting cement incl. admixtures (in place) | per ton | 596.00 CAD |

**Curtain grouting above ground** (for ground water control only)

| Mobilization and demobilization (to and from grouting area) of plant and equipment for drilling and grouting above ground | each campaign | 2,500.00 CAD |
| Drilling max. 71 mm dia., max. length = 5,00 m | per m | 50.00 CAD |
| Drilling max. 71 mm dia., length = 5,01-10,00 m | per m | 54.00 CAD |
| Drilling max. 71 mm dia., length = 10,01-20,00 m | per m | 64.00 CAD |
| Drilling max. 71 mm dia., length = 20,01 - 30,00 m | per m | 79.00 CAD |
| Grouting connection | per No. | 1,430.00 CAD |
| Grouting cement incl. admixtures (in place) | per ton | 490.00 CAD |

**UNIT RATE FOR SHOTCRETE**

**Fixed costs**

| Mobilization and demobilization of plant and equipment for applying additional shotcrete in tunnel or above ground (not applicable to shotcrete to overbreak in tunnel) | each campaign | 2,500.00 CAD |

**Applying shotcrete**

| Mass shotcrete | each m³ | 465.00 CAD |
UNIT RATE FOR DISPOSAL OF ROCK OVERBREAK

All rock classes and locations
Disposal of rock overbreak (solid rock) each m³ 55.00 CAD

UNIT RATES FOR PUMPING TREATMENT AND DISPOSAL OF WATER

Plant and installation per additional litre per second per unit 6,000.00 CAD <30 l/s
4,000.00 CAD 30 to 150 l/s
3,100.00 CAD >150 l/s

Running cost pumping and disposal
Tunnel Pumping and disposal of water (with treatment) during excavation and first pass lining only per m³ 0.35 CAD
Intake Pumping and disposal of water (with treatment) per m³ 0.15 CAD

1.0 GENERAL

1.1 PROJECT OVERVIEW

The proposed Niagara Tunnel Facility aims to convey an inflow of about 500 m$^3$/s from the Niagara River to the Ontario Power Generation power canal system. This new additional system shall be capable of directing the desired flow under all operating conditions and subject to the specified environmental restraints.

This document shall be read in conjunction with the document titled “Structural Design Analysis” for the two structural component covered by this document, namely the intake approach wall and the accelerating wall.

1.2 DEFINITION OF SYSTEM

The proposed project, layout of which is given in Concept Drawings provided by OPG, will consist of the following key component structures:

(a) Intake Channel and Approach Wall
(b) Accelerating Wall
(c) Intake Structure
(d) Diversion Tunnel
(e) Dewatering Station and associated work
(f) Outlet Structure

1.3 SCOPE

This Draft Design Basis and Method Statements document is for the specific elements (a) and (b), namely the Intake Approach Wall and the Accelerating Wall only.

This document covers the main aspects for design and construction of these structures including the following:

- Preliminary layout of works
- Design approach
- Codes and standards
- Outline specifications
- Construction techniques
- Layout of construction equipment to install the walls
- Sequencing of the work

The Design Basis and Method Statements for the remaining elements of the Niagara Tunnel Facility Project will be addressed by other relevant documents elsewhere in the Proposal submission.
2.0 INTERFACING SYSTEM

The Intake Approach and Accelerating Walls are to interface with and connect to existing structures and facilities as a part of the intake system structures. The Intake Approach Wall and the Accelerating Wall are to be joined to the designated piers of the INCW with minor modification and extension of the structure. The Intake Approach Wall shall be blended into the existing SAB2 intake wall.

The Intake Structure and Outlet Structure will provide control for the water flow between the diversion tunnel and the existing power canal.

Service gates will be located in the Intake and Outlet Structures for dewatering the diversion tunnel.

3.0 FUNCTIONAL REQUIREMENTS

3.1 FUNCTIONAL OBJECTIVES

The Intake Approach and Accelerating Walls shall be capable of directing smoothly continuous supply of water to the Intake Structure to meet the designed flow, while meeting the specified hydraulic and environmental requirements under all operational conditions.

3.2 DAM SAFETY REQUIREMENTS

The structures shall be capable of retaining the stored volume and to pass flows around and through the structure in a controlled manner.

There could be a number of modes of failure of the wall but the probability of such is extremely remote if properly designed. It is expected that failure, if occurring, should be limited to minor displacement or tilting of walls at which instance it could be easily detected and remedied accordingly. The need to close the tunnel in those situations is highly unlikely.

The potential hazard resulting from failure of the Intake Approach and Accelerating Walls appears to be very low as it is unlikely that there is any loss of life resulting from its failure and that the economic value of other losses will also be minimal outside the loss of power generation.

4.0 PERFORMANCE REQUIREMENTS

4.1 LAYOUT DESIGN

The layout design shall:

1. Direct the prescribed quantity of water (about 500 m$^3$/s) drawn from the Niagara River to the existing power canal system under operating conditions, with minimum head loss and high structural reliability;
2. Ensure an uninterrupted flow of water under all adverse climatic and environmental conditions (i.e. shall provide satisfactory performance for both open water and ice conditions),

3. Satisfy all conditions imposed by the hydraulic, environmental, operational and economic requirements;

4. Consider all safety requirements,

5. Allow provisions for periodic inspection, maintenance and ease of repair or even replacement of structural modules under operating conditions if necessary,

6. Allow construction of the structures, within the limit of the scheduled construction period, in a logical sequence,

7. Permit suitable means of foundation preparation with minimum time required for underwater and in-river operations,

8. Take into account the restrictions on marine construction scheduling as imposed by the Ministry of Environment (MOE).

4.2 DESIGN AND SERVICE LIFE

The tunnel lining system, intake structure and outlet structure shall be designed for a service life of 90 years. Other elements, such as the accelerating wall, approach wall and the intake channel, which are not specifically required to be designed for a 90-year service life, shall be designed to applicable and appropriate codes, guidelines and standards that are commensurate with their intended purpose.

5.0 SAFETY REQUIREMENTS

5.1 STRUCTURAL INTEGRITY

The structure shall be designed in accordance with the Codes and Standards listed in Section 14.0 to ensure adequate structural integrity and safety for all the conditions under which the system is intended to function.

5.2 INDUSTRIAL SAFETY

During underwater construction, in-service inspection and maintenance of the structures, safety of the divers or personnel shall be ensured. The diving operation shall be conducted in a safe manner according to CSA Z275.2.

The layout design of the structures shall take into account the safety of the operating and maintenance personnel.

5.2 SAFETY BY DESIGN

Improving the safety environment of the construction site will reduce worker injuries and save time and cost. But, safety practices alone are not enough to reduce accidents because they are unable to remove hazards inherent in a facility’s design or required construction sequences.
Safety measures considered and incorporated in the schematic and design development phase will have direct impact to improve the safety environment of construction workers on the job site. Many designer decisions could also impact the safety of end users, maintenance and repair workers.

In addition to reduction of construction worker injuries and associated costs, pre-project safety planning is also important to implement design features to reduce re-design, rebuild, maintenance, and operating costs.

A safety analysis conducted during design phase is an effective means of identifying unnecessary hazards in the project design. Many of these hazards may be “designed out” through the use of alternative components, systems, or construction methods. Design suggestions will be used to control or to eliminate the hazards.

A computerized design aid may be used to conduct a comprehensive and systematic construction safety analysis during the design phases of the project. The following should be investigated:

1. identification of construction hazard
2. summarize and prioritize hazards
3. investigate lessons learnt and design solutions
4. document project hazard related decisions
5. report on hazard tracking, owner acceptance and residual risk

It is also important to utilize a management tool to ensure comprehensive design team involvement.

As the design proceeds, the contractor and specialist contractors will be included in the design process to ensure that due consideration for constructability, especially for in-water works, will be made in the design and detailing of the work. The input from the contractors will also enable any construction in the water to be carried out safely and will comply with the best and most up-to-date construction practice for these works. The design will be completed through an iterative process that includes these parties.

6.0 STRUCTURAL REQUIREMENTS

6.1 LOADS

The structure shall be designed to withstand all temporary, permanent, construction, environmental, normal, unusual and extreme loads, in all possible combinations.

All structural components shall have adequate capacity to safely sustain the prescribed design loads.

6.1.1 Design Loads

The types of loads for which the structures are to be designed include the following:
(a) Dead Loads (D)  
All permanent masses of the structural components, all permanent construction materials,  
including the permanently located attachments and equipment systems, if any.

(b) Operating Water Pressures (H)  
The external water pressure exerted by water above ground is governed by the specified  
maximum water levels. When used as stabilizing force acting on the structure in a stability  
analysis, these forces must be conservatively estimated.

(c) Design Flood (F)  
The water level under inflow flood scenario varies between the 200-year flood and the  
Probable Maximum Flood (PMF) as prescribed in the OPG Invitation document.

(d) Hydrostatic Uplift (U)  
Uplift pressure exists through cross section within the wall structure, at the interface between the  
wall structure and the foundation, and within the foundation below the base.

(e) Soil and Silt Pressures (S)  
Earth pressures against the structure may occur where backfill is deposited in the exaction.  
However, it was stipulated by OPG that Passive pressure due to backfill shall not be  
considered. Silt pressures are considered in the design if suspended sediment measurements  
indicate that such pressures are expected.

(f) Wind Load (W)  
Wind loads applicable at the site location should be computed based on a sufficient low  
probability factor. For construction design condition (e.g. prior to backfill), wind pressure  
acting on the structure may be based on a higher probability factor. Usually, wind load is not  
a governing factor for massive concrete structures.

(g) Ice Load (I)  
The structure is to be designed to withstand the forces generated by ice movement against it.  
Ice forces may include dynamic loads generated by ice floes striking the structure, and static  
loads generated by thermal expansion or contraction of the ice and by fluctuations in the  
water levels.  
The magnitude of thermal ice load is governed by a number of controlling factors such as ice  
thickness, shoreline confinement, water velocity, water level fluctuation, rate of temperature  
rise, etc.

(h) Seismic Loads (E)  
The earthquake loadings used in the design of the structure are based on design earthquakes  
and associated ground motion parameters determined from seismological evaluation for the  
specific site. Where site specific study has not been conducted, seismic zone maps of the  
National Building Code proposed for the 2005 revision are to be used.

Two levels of seismic loads are usually considered for the design: (a) the Maximum Design  
Earthquake (MDE) having an extremely low probability of annual exceedence, and (b) the
Operating Basis Earthquake (OBE) used in conjunction with ice loading and having a probability of annual exceedence of 1 in 200.

(i) Hydrodynamic Loading (H_D)
Hydrodynamic loading includes the effects of the maximum transient heads in the tunnel during the gate closure. Loads due to water hammer shall be provided by a hydraulic study. Unlike the Intake Structure and the Outlet Structure, the Intake Approach and Accelerating Walls are not subject to such dynamic transient loads.

(j) Construction Loads (C)
Construction lifting loads shall be dead weights in air or under water plus 50% for impact allowance during handling, lowering, barging, launching and controlled sinking operations of the precast modules. Construction loads due to mobile or tower cranes will also be considered where appropriate.

(k) Other Loads
In general, loads induced by other factors such as temperature are not significant in mass concrete gravity structures. Hence, these may only be considered where deemed necessary.

6.1.2 Load Combinations

All combinations of loads that may act simultaneously during construction, normal plant operation or abnormal environmental conditions shall be considered.

The loading conditions considered in concrete structure designs and overall structural stability analysis shall include but not limited to the following:

1. Loading Case No. 1 – normal loading condition – Construction
   Any combination of loads that may act simultaneously during the construction period, including lifting and handling loads, crane loads for construction activities, etc.

2. Loading Case No. 2 – normal loading condition – Summer Operating
   Any combination of loads that may act simultaneously during normal operation.

3. Loading Case No. 3 – normal loading condition – Ice Load
   Any combination of loads that may act simultaneously due to ice loading effects on the structural components.

4. Loading Case No. 4 – normal loading condition – De-watering
   Any combination of loads that may act simultaneously during planned dewatering or emergency shutdowns of the tunnel facilities.

5. Loading Case No. 5 – unusual loading condition – IDF^1
   Any combination of loads that may act simultaneously during a 200-year flood.

6. Loading Case No. 6 - extreme loading condition – PMF^2
   Any combination of loads that may act simultaneously during this extreme environmental event which has a low probability occurrence.

^1 IDF = Inflow Design Flood

MH-3001-00
Date: May 11, 2005
7. Loading Case No. 7 – extreme loading condition – MDE\(^3\)
   The Intake Approach and Accelerating Walls, being a conventional structure (i.e. not dam safety related), shall be designed to satisfy the requirements stipulated in the National Building Code of Canada.

8. Loading Case No. 8 – extreme loading condition – Ice Load and OBE\(^4\)
   Any combination of loads that may act simultaneously in an unlikely event that an earth tremor occurs during peak winter season. As the probability of the combination of these two environmental events occurring simultaneously is low, the earthquake load is decreased appropriately.

The most critical design condition for various loading cases shall be assumed.

6.2 DESIGN CRITERIA

6.2.1 Stability Requirement

Sliding stability of the structures shall be verified by limit equilibrium method using un-factored loads. The computed factors of safety against sliding, and resulting stresses along any critical sections within the structure or at the base shall not exceed the minimum acceptable factors of safety and allowable working stresses specified for the normal, unusual and extreme load combinations.

6.2.2 Required Strength

The reinforced concrete hydraulic structures shall be designed in accordance with the Strength Design Method. The structural members will have a required strength to resist design loads and the factored load combinations specified in Sub-Section 6.1.1 and 6.1.2.

The load factors as prescribed in CSA A23.3 shall be applied and the total factored design load shall be increased by the hydraulic factor \( H_f = 1.3 \). The hydraulic factor is used to improve crack control for massive hydraulic structures which usually are lightly reinforced.

The hydraulic factor is not applicable for sliding or overturning stability analysis.

6.2.3 Design Strength

The strength of a structure or individual member must exceed the demand (required strength) for all foreseeable loads without failure or significant distress. The nominal strength must be reduced by a resistance factor to account for the variability in the strength. For this purpose, the resistance factors prescribed in CSA A23.3-94 shall be applied.

\(^2\) PMF = Probable Maximum Flood

\(^3\) MDE = Maximum Design Earthquake

\(^4\) OBE = Operating Basis Earthquake
6.2.4 Serviceability Requirement

An adequate uninterrupted supply of water to the intake tunnel must be assured. Structural members shall be proportioned to minimize deflection limit and the foundation will be designed and constructed with adequate measures to minimize possible settlement.

7.0 DESIGN CONSTRAINTS

The location, dimensional geometry, and transitional shape of the Intake Approach and Accelerating Wall systems are fixed as defined on the Concept Drawings. Extension of the respective INCW piers to connect these two walls will be adjusted during the final design stage as determined by the final tunnel configuration and other more accurate survey data at the site.

For design purpose, OPG stipulated the following limitations:

1. Passive pressure due to backfill shall not be considered.
2. Cohesion at the concrete rock interface shall not be assumed.
3. Rock anchors shall not be used to provide the required stability of gravity structures.

8.0 DESCRIPTION OF TYPE OF STRUCTURES

The Intake Channel, and Approach and Accelerating Walls are positioned upstream of the INCW Structure. The dimensional geometry, alignment, and top elevations of these walls are fixed as defined in the Concept Drawings provided by OPG.

The Intake Approach and Accelerating Walls shall be mainly composed of a series of structurally independent reinforced concrete modules, filled with rock-fill materials and capped with concrete cover slab. Transitional sections to the existing INCW Structure and to the gravity wall of the existing tunnel no. 2 shall be cast-in-place concrete wall sections.

The precast concrete modules shall be designed to have vertical keys for interlocking with adjacent modules to improve retaining back-fill materials and overall lateral stability.

These precast wall units shall be arranged in such an alignment to form a smooth surface to direct the flow of water into the Intake Structure.

9.0 CONSTRUCTABILITY REQUIREMENTS

9.1 CONSTRUCTION METHODS

The effects of construction sequence and methods shall be considered including the following:

1. Application of conventional design and construction methods, if all possible, shall be considered.
2. The effects of special construction material handling methods and equipment including floatation assistance systems, large capacity crane, etc. shall be evaluated.
3. The effects on the structural system due to the maximum variance in degree of levelling of foundation pads shall be taken into account in the design.

4. The timing and method employed for demolition of the existing accelerating wall and disposal of materials shall be carefully considered to minimize environmental impact and off-site disposal.

5. During the design process the contractors and key subcontractors will be involved on an ongoing basis to ensure that designs are developed that are practical, constructable and meeting standards. Worker safety will also be a key design consideration.

6. Marine construction period should be kept to a practical minimum in accordance with the restrictions on the marine construction scheduling imposed by MOE.

7. Construction activities at the Intake Channel, and the Approach and Accelerating Walls must not hinder the efficient movement of ice in the vicinity of the INCW.

8. The cofferdam arrangement shall be designed to minimize the interference into Bay 2 of the INCW.

9. Blasting where needed shall be controlled to ensure that the rock beyond the excavation limits is not damaged or de-stabilized by the blasting operation. Blasting velocities shall be carefully monitored to ensure operation of existing equipment will not be affected.

10. Most importantly, the integrity of the foundation of the INCW structure must be fully secured during the blasting activities for the Intake Channel, as well as for the excavation associated with the construction of the Intake Structure and the extension of Piers 1, 2 and 5.

9.2 CONDITION SURVEYS

Through careful planning and use of proper construction techniques, the impact on existing structures and systems by the performance of the construction work should be minimal.

For verify the impact with specific data, condition surveys of existing structures in the near vicinity of the construction sites will be conducted before and after the construction work is complete. These condition surveys will be undertaken by independent qualified consultants employed by OPG.

Adjustment of construction methods may be necessary upon review of some preliminary condition survey reports.

9.3 HYDROGRAPHIC SURVEYS

The preliminary design of the walls is based on lakebed survey results or as shown on drawings provided by OPG. To permit detailed design to proceed, an accurate measurement of the lakebed at suitably close intervals must be carried out. The information provided from dipping or sonar measurements should enable the engineer to ascertain the actual lake bottom along the alignments of the walls. By this the cement sandbag padding requirements as well as the sizes of the precast wall elements can be finalized and any alteration or customization could be made to the concrete blocks prior to them being manufactured, and the engineer and the contractor could act accordingly.
10.0 MAINTAINABILITY REQUIREMENTS

The targets stipulated for these structures will ensure that the maintenance requirements are reduced to the practical minimum.

The layout design shall ensure suitable means of access for personnel and materials for the purpose of efficient operation, maintenance and inspection.

11.0 CONCRETE CONSTRUCTION

The concrete material to be used for the construction of these structures shall be in accordance with the appropriate specification, standards and manuals listed in Sub-Section 12.1 and 12.2.

All concrete is to have the specified 28 days compression strength, water cementing material ratio, and air content in accordance with the requirements of CSA Standard A23.1-00.

11.1 DURABILITY REQUIREMENTS

Concrete in water passage shall be designed to be resistant to the abrasive action of water flow, entrained ice and debris. Hence, concrete with low water/cementitious materials ratio and having adequate strength shall be used.

Based on information provided, it is understood that concrete made with a cement that provides sulphate resistance is only required for the annular grout and reinforced concrete lining, but not these concrete structures.

11.2 CONSTRUCTION TECHNIQUES AND EQUIPMENT

Construction of the walls will generally include the padding of the lakebed and level the placement areas with cement stabilized sandbag, which may involve the use of divers. After confirmation of the stability and accuracy of the padding layer the first layer of precast wall units will be installed. The bottom of the wall, including the void within the padding sandbags will be filled with mass concrete infill to the level shown on the drawings. The remaining layer(s) of the wall will then be installed and rockfill placed inside the voids in the wall, and reinforced concrete capping will be installed. It is expected that construction using barges (in-water activities) and cranes (land activities) will be required to construct the various components of the walls. Where barge is used, appropriate docking and storage facilities should be constructed at the site, and all extra loadings arising from such shall be included in the design of the walls if an impact is identified.

There are areas along the walls where mass concrete infill will be required, primarily to stabilize the bottom of the wall and the sandbag base on which the precast units will be installed.

Prior to the placement of mass concrete in-fill, the area shall be cleaned of silt and debris.

When the mass concrete in-fill area cannot be kept water free, procedures for underwater concreting shall be established to include concrete mix design, appropriate admixtures,
placement schemes, inspection plan, and concrete sampling plan to ensure concrete placed is competent. When the concrete surface has been brought above the water line, all the laitance must be removed from the surface of the concrete before normal concrete placing continues.

For constructing extension of concrete structural elements, the surfaces of the existing component shall be thoroughly scaled. And, prior to placement of new concrete, the concrete surfaces shall first be cleaned by sandblasting, followed by an air-water jet to remove all loose and adhering contaminants to ensure full bonding will be achieved.

During construction the contractor shall adhere to all environmental requirements as stated elsewhere in the contract, and comply with necessary restrictions that may be in place for working near a tourist site. Any area disturbed by construction operations shall be reinstated properly as shown on the drawing, as directed by OPG, or to the pre-construction conditions.

12.0 CODES AND STANDARDS

12.1 CODES, REGULATIONS AND LAWS

The requirements of the following codes, regulations and laws shall be referred to, where applicable:

3. CSA Standard CAN3-A23.3-94: Design of Concrete Structures
5. Dam Safety Regulation under the Lakes and Rivers Improvement Act (Proposed Draft), Ministry of Natural Resources (November 2001)

12.2 OPG SPECIFICATIONS, STANDARDS AND MANUALS

The structure shall be designed and constructed in accordance with the following standards and specifications:

1. Niagara Tunnel Facility Project - Invitation to submit Design/Build Proposals, Ontario Power Generation (Amendment 1, February 2005)
2. Dam Safety Guidelines, Canadian Dam Association (January 1999)
3. Guidelines and Criteria for Approval under the Lakes and Rivers Improvement Act, Ministry of Natural Resources (Draft, May 1997)
4. CSA Standard CAN3-A23.1-94: Concrete Materials and Method of Concrete Construction
5. CSA Standard CAN3-A23.2-94: Methods of Test for Concrete
13.0 PRELIMINARY DESIGN DESCRIPTION

13.1 GENERAL

The Intake Approach and Accelerating Walls have been developed based on the precast reinforced concrete modular system concept. For each module, the basic structural system is an open rectangular box structure. The size of these units is determined mainly based on practical and economical limitations related to transportation requirements. Specifically, the governing factors are the maximum width and gross weight of each modular unit.

The respective wall will be constructed by stacking up either two or three units. The stacked modules are to be filled with rock-fill materials and subsequently fully covered with a concrete slab on the top of the wall.

13.2 FABRICATION

The Intake Approach and Accelerating Wall concrete modules shall be prefabricated under controlled environment in the dry.

13.3 FOUNDATION PREPARATION

The overburden at the Intake Approach and Accelerating Wall foundation location shall be excavated to ensure all loose materials are removed to the exposed rock level.

13.4 PLACEMENT OF SUPPORT PAD

Cemented sand bags used for the supporting pad shall be placed in such a manner that the allowable degree of levelling will be achieved. The variation in the top surface elevation for adjoining interlocking modules shall be less than 40 mm. The maximum relative elevation difference in the finished top surface of the entire wall shall be less than 150 mm.

13.5 ROCK-FILL

Rock-fill materials to be placed within the precast concrete modular units shall consist of clean rock fragments and shall be free from organic materials.

Rock-fill shall be uniformly graded in size up to a maximum size appropriate for this application.
13.6 CONCRETE COVER SLAB
The Intake Approach and Accelerating Walls shall be fully covered with a concrete slab. These cover slabs may be cast-in-place or precast units.

13.7 BACK-FILL
Back-fill materials behind the Intake Approach Wall shall be clean rock fragments and shall be free-draining. No back-fill shall be placed behind any concrete modular unit until it is fully rock-filled first.

Back-fill to form the final prescribed slope shall be placed only after the concrete cover slab is well in place.

14.0 DESIGN ANALYSIS

14.1 CODES, STANDARDS AND SPECIFICATIONS
The Intake Approach and Accelerating Walls will be designed in compliance with the codes, standards and specifications listed in Section 12.

14.2 DESIGN METHODS AND PROCEDURES
The structural systems will be designed by using recognized methods and procedures, which include the established and coded computer software in performing the structural analysis as appropriate for the design.

14.3 STABILITY ANALYSIS
Stability is evaluated in a manner similar to a conventional gravity retaining wall. For stability calculations the interlocking precast concrete modular system is assumed to behave as a coherent block. The system must be stable against sliding along the base of the structure, overturning about the toe of the wall, and bearing capacity failure of the foundation.

15.0 INTAKE CHANNEL

15.1 EXCAVATION
The excavation of the sides of the Intake Channel shall be done by employing line-drilled and controlled blasting to ensure that the surrounding rock beyond the excavation limits is not damaged or de-stabilized. Any rock outside the requisite excavation lines which may be damaged by the construction works shall be removed and backfilled with sound concrete sufficiently anchored back to integral solid rock.

Excavation of the Intake Channel shall be done in two stages. The first stage consists of excavation of the two shallow approach sections in the wet up to designated elevation. The second and final stage will be done in the dry condition provided by a cofferdam.
For the deep excavation area, multiple grout curtains will likely be required to ensure that the area is sufficiently dry throughout the period of excavation and construction of the Intake Structure. If found necessary, rock anchors may be installed to assure no detrimental effects on the rock foundation of the INCW Structure will occur.

15.2 EFFECTS ON INCW STRUCTURE AND SYSTEMS

Excavation by blasting at close proximity of the INCW Structure shall be carefully planned and close control shall be exercised to ensure that the integrity of the control structure and its foundation will be maintained.

In general, ground vibration from construction sources such as blasting will depend on the blasting method and the seismic propagation characteristics of the site. Vibration-induced damage thresholds are usually expressed in terms of peak particle displacement, velocity or acceleration, and sometimes include a frequency-dependent factor.

It is most usual for peak particle velocity to be used, because it has been found to be the best correlated with case history data of damage occurrence and because it has a theoretical underpinned inasmuch as the strain induced in the ground is proportional to the particle velocity.

For this reason, strategically located measurements will be made to monitor the vibration level on the existing structures. The recorded data will be assessed against appropriate vibration damage thresholds to be established by expert judgement based on specific site knowledge and previous case history data.

If necessary, trial blasts should be carried out where initial desk studies show that nearby structures could be at risk or that the sensitivity of system is high. The trials should be designed with a clear concern for the factors that will influence the induced peak particle velocity during the excavation works.

16.0 DEMOLITION OF EXISTING ACCELERATING WALL

16.1 REFERENCE DRAWINGS

Typical details of the existing Accelerating Wall which is to be demolished and removed are shown in reference drawings provided by OPG.

Field survey and inspection of the existing conditions to verify all details and dimensions will be conducted prior to execution of the demolition work.

16.2 Demolition Sequence

Means and methods used in demolition of the existing timber-cribed Accelerating Wall shall be such as to minimize impact on the operation of the INCW. All in-river activities shall meet all the environmental requirements and safety program established by OPG.

Demolition of the timber-cribed structure shall be undertaken section by section starting from the far end working towards the INCW structure.
For each section, demolition will begin with breaking and removing the concrete cover slab. After rock-fill is removed to designated level or as agreed by the engineer, the timber cribs will be saw cut across the mid height. The top half will then be lifted and removed. The same procedure is followed for removing the bottom half. Throughout the removal process the timber crib wall must be stabilized by rockfill against being washed away in the current. All remaining rockfill left after the timber is removed shall also be picked up immediately.

16.3 DISPOSAL

All structural materials of the existing Accelerating Wall shall be removed from the Niagara River and disposed to sites approved by OPG. Rock fill materials of good qualities may be reused for construction of the new Accelerating Wall subject to approval by OPG.

17.0 SEQUENCING OF WORK

The recommended sequences of construction as presently envisage are as follows:

1. The existing Accelerating Wall is removed.
2. The new Accelerating Wall is constructed.
3. Part of the east Intake Approach Wall is constructed.
4. Concurrently with the above activities, excavation of the two shallow sections of the Intake Channel is carried out in the wet.
5. After the completion of the new Accelerating Wall, a cofferdam is installed at the location where the last deep section of the Intake Channel is to be excavated. An ice protection groyne is constructed.
6. The excavation of the last deep section of the Intake Channel is done in the dry, followed by the construction of the extension of the INCW pier 1 and 2.
7. Part of the west Approach Wall is constructed in the dry.
8. After the sectional service gates for the Intake are in place and with balanced water pressure on each side of the cofferdam, the groyne and the cofferdam are removed.
9. The construction of the Intake Approach Wall is complete with backfill to the desired level and slope defined.

The above construction sequencing is feasible given the information and preliminary requirements known to-date. The Contractor shall verify all details and dimensions of the existing site, adjacent structures prior to execution of the site work. If during the course of work, existing conditions are found to deviate from those assumed for design, the engineering consultants shall be notified. Additional analysis or alternate design may be necessary before proceeding further with the work.

MH-3002-00
Date: May 11, 2005
1.0 GENERAL

1.1 PROJECT OVERVIEW

The proposed Niagara Tunnel Facility aims to convey an inflow of about 500 m³/s from the Niagara River to the Ontario Power Generation power canal system. These associated works will provide the necessary infrastructure to support the construction of the tunnel and access shafts, the intake structure, outlet structure and other associated works.

1.2 GENERAL DEFINITION OF CIVIL REQUIREMENT

The proposed project, layout of which is given in Concept Drawings provided by OPG. The civil components of this project covered under this document consist of the following:

1. Temporary Facilities, including all Laydown Areas;
2. Roads and Parking Areas;
3. Fencing and gates; and
4. Stockpiles.

This document will also cover the following work components as they are not covered in other sections of this proposal:

5. Demolition and disposal of the Dewatering Structure at the Pump Generation Station (PGS);
   and
6. Relocation of the waterline as a result of the removal of the dewatering structure.

1.3 SCOPE

This Design Basis and Method Statements document is for the above-named work components for the contractor’s works areas, the Intake and Outlet construction staging areas as well as the final stockpile area. Also covered is the works related to the removal of the dewatering structure outside the PGS.

The following aspects of design and construction will be covered

1. Layout of works;
2. Design Approach;
3. Codes and standards; and
4. Outline specifications
2.0 FUNCTIONAL REQUIREMENTS

2.1 GENERAL

The following is a summary of the various elements of the civil and miscellaneous works for the construction staging areas at the intake and outlet structures.

2.1.1 Temporary Facilities

At the intake a construction laydown area will be placed to the south of Niagara Parkway. This facility will be used in conjunction with all associated works at the intake.

At the outlet the construction offices will be located adjacent north south portion of the temporary access road. This site will be fully serviced by temporary utilities from Stanley Avenue. In addition Material Yards will be placed throughout the site within designated areas and will be fully accessible. All areas to be used as works areas or storage will be entirely within the properties of OPG. Areas identified as reserve areas or within prohibited zones (such as those under the overhead power lines) will remain untouched and protected.

2.1.2 Roads and Parking Areas

At the intake site a temporary roadway is being constructed to allow access to the site from Portage Road to the construction laydown area and across Niagara Parkway to the construction area at the intake and will eliminate any need for construction traffic to utilize Niagara Parkway.

At the outlet site a new permanent paved access road is being constructed from Stanley Avenue that could be used to service the works area at the part of the site. However only approximately 180 m of this road will be built and will remain in-place until past the end of construction of this project. Beyond the limit of this pave road a temporary roadway is to be constructed to provide access to the material stockpiling area and all areas at the outlet location.

Parking at location near site offices will be provided, as shown on drawings MH-6008 and MH-6009, including potential areas that may be expanded to be used for this purpose. These areas may or may not be paved.

Relocation of recreation trails at the intake areas will be completed also as per drawing no. MH-6008.

2.1.3 Fencing

Fencing will be chain link for all construction and any other areas to eliminate interference between the public and the construction activity.

Hoardings will be placed at locations designated as being close to pedestrians primarily along the Niagara Parkway, as shown on drawing MH-6008.

2.1.4 Stockpiles

During the excavation of the tunnel approximately 2.0 million cubic metres of material will be stockpiled between the two power canals as shown on MH-6009. These stockpiles will be
approximately 5 to 6m in height with 1 (vertical) to 2.5 (horizontal) side slopes and with the top surface level and graded.

According to the Draft Design/Build Agreement and Concept Drawings, specifications for the excavated material potentially contaminated with BTEX are provided. This material is to be placed on a temporary storage pad until chemical testing is completed to determine how this material is to be managed. The temporary storage pad is located in the northeast corner of the main disposal area. Accordingly, runoff in this area will be sent to the retention pond and treated after sampling, if required. The Draft Design/Build Agreement further states the height, compaction, drainage, setback and slope requirements. However, OPG’s “Management of Excavated Material” dated December 2004 and OPG’s “Management Plan for BTEX” dated December 2004, provides more detail for the permanent and temporary stockpiling of specific rock formations. In particular, the Draft Design/Build Agreement requires a temporary storage area for material potentially contaminated with BTEX and the “Management of excavated Material” requires that the material potentially contaminated with BTEX be permanently stored without temporary storage requirements.

2.1.5 Demolition of Dewatering Structure at Pump Generation Station

As part of the project the Contractor will remove the existing reinforced concrete structure located at the PGS canal including all equipment associated with the gate. The removal of the structure will open up the channel cross section and will increase the flow capacity of the channel to accommodate the additional water brought through the new tunnel. Information regarding the existing dewatering structure include as-built drawings, are provided by OPG.

2.1.6 Relocation of the Waterline

An existing waterline currently crosses the PGS Canal via the dewatering structure, and mounted on the deck surface of the structure. Due to removal of the structure, the waterline has to be re-routed along the west bank of the canal and cross the canal via the road outside the PGS, and reconnected to the section of the waterline on the east bank of the canal. An alternate solution of installing a utility bridge will be considered and evaluated along with the OPG staff to develop the most cost effective and constructable solution.

As the waterline is owned by OPG, discussion with OPG has to be carried out to ensure that any supply disruption, timing of the disruption, temporary cut-off and reconnect arrangements, work inspection and the like are to be conducted properly and with sufficient advance notice.

3.0 REQUIREMENTS

3.1 GENERAL

The following is a detailed summary of the requirements that guided the development of the design of the temporary facilities.

3.1.1 Layout Design

The layout design shall:
1. Provide safe and reliable access to each of the intake and outlet construction staging areas, with proper intersection layout with main public roads and highways.
2. Ensure a safe and reliable stockpiling area for all excavated materials from the tunnel.
3. Ensure that all environmental protection requirements are complied with such as during clearing and tree removal, and that no deleterious materials are introduced into the water and subsoil systems.
4. Take into account all restrictions placed on the excavated materials and ensure compliance with all agree to regulatory measures.
5. Consider all safety and security requirements, including those to trespassers.
6. Allow provisions for periodic inspection, maintenance and ease of repair or even replacement of any of the temporary works if necessary.
7. Allow construction of all temporary works within the limit of the scheduled construction period, in a logical sequence and prior to the core works.
8. Actively involves the contractor throughout the design process to ensure that all their requirements, such as sufficiency of areas, construction production rates, and the like, are duly addressed and updated from time to time.

4.0 CONSTRUCTION RELATED ISSUES

4.1 CONSTRUCTABILITY AND CONSTRUCTION METHODS

The effects of construction sequence and methods shall be considered including the following:

1. Application of conventional design and construction methods, if all possible, shall be considered.
2. Movement off all construction and excavated materials shall ensure the necessary containment and mitigation of any contamination of the existing ground and the canal system and shall be in compliance with the Environmental Management Plan.
3. Tire washing facilities, noise abating devices, properly painted hoarding, and the like, should be in place to avoid any adverse impact to the neighbouring road, residents and visitors.
4. The removal of the dewatering structure requires significant planning and coordination with OPG staff, and observing all the environmental requirements of working in the water. The need to remove construction debris from the canal would probably dictate the use of specialized equipment that would generate as little small fragment of construction debris as possible.

4.2 CONSTRUCTION EQUIPMENT

Only conventional construction equipment are expected to be used in all civil engineering works, except due consideration of the environmental protection should be made when removing the dewatering structure. Collecting device may be considered in the deck removal to minimize contamination of the water resulting from the demolition work, and the intention is to have large block of the structure removed and lifted off instead of fine breaking processes.
The use of barge stationed in the canal as a working platform will be considered, and discussion will be held with OPG to ensure all issues are resolved if this method is to be adopted.

5.0 MAINTAINABILITY REQUIREMENTS

Most civil works are required to be in place and function throughout the entire construction period and therefore must be properly maintained. The targets for all works will ensure that the maintenance requirements are reduced to the practical minimum. The layout design shall ensure suitable means of access for personnel and materials for the purpose of efficient operation, maintenance and inspection of all works.

6.0 CODES AND STANDARDS

6.1 GENERAL

The following is a detailed summary of the regulations and laws that govern the design development and the commitment to the safety.

6.1.1 Codes, Regulations and Laws

The requirements of the following codes, regulations and laws shall be referred to, where applicable:

1. OPSS (Ontario Provincial Standard Specifications)
2. CSA Standard Z107.0-00 (Standard for Certification of Noise Barriers February 2000)
3. CAN/CSA-S6-00 (Canadian Highway Bridge Code)
4. Other CAN standards, see applicable specifications included
5. Other CSA Standards, see applicable specifications included

6.1.2 OPG Specifications, Standards and Manuals

The shall be designed and constructed in accordance with the following standards and specifications:

1. Niagara Tunnel Facility Project - Invitation to submit Design/Build Proposals, Ontario Power Generation (Amendment 1, February 2005)
2. Ontario Provincial Standard Drawings (OPSD)

6.1.3 Conditions of Approval

Generally, during design, construction and post-construction activities, the Contractor shall work in a manner that protects health and the environment and in compliance with the following:

2. The requirements of the Environmental Assessment Approval, dated October, 14, 1998;
3. The requirements of Approvals obtained by OPG;
4. The requirements of the Environmental Approvals and Third Party Information, dated March 2005;
5. The requirements of Approvals to be obtained by OPG or the Contractor;
6. The requirements of the Draft Design/Build Agreement;
7. The requirements of the Community Impact Agreement, dated December 22, 1993;
8. This Environmental Management Plan;
9. Plans submitted to OPG as outlined in this document and Draft Design/Build Agreement;
10. Applicable statutes, laws and regulations;
11. OPG’s Environmental Management System; and,
12. The requirements of federal, provincial and municipal agencies.

In order to meet all of the environmental requirements for the Project, as outlined above, a compliance plan has been developed. This plan provides the specific procedures that will be completed during all phases of the Project to ensure compliance with the Draft Design/Build Agreement, Community Impact Agreement, Environmental Assessment, applicable laws, regulations and guidelines, approvals, agency requirements and applicable Project documentation. To effectively document and explain the compliance procedures, this section has been divided into the three phases of the Project: design, construction and post-construction. The compliance plan utilizes procedures such as environmental audits, risk management analysis, quality assurance/quality control, and environmental inspection, monitoring and training, to ensure compliance.

7.0 PRELIMINARY DESIGN DESCRIPTION

7.1 GENERAL

The preliminary design and development of plans for the temporary civil works, which in this case also include the removal of the dewatering structure at the outlet PGS Canal and the relocation of the waterline, have been developed based on the requirements given in the drawings provided by OPG, particularly the Owner’s Mandatory Requirements and subsequent clarifications, as well as applicable standards as outlined in the specifications attached herewith.

7.1.1 Temporary Facilities

- Intake Temporary Facilities:

  At the intake a construction laydown area will be placed to the south of Niagara Parkway. This facility will be used in conjunction with all associated works at the intake. This site will be approximately 182 m x 76 m. It will be fenced and a lockable gate provided for security. Their surface will be graded stone and maintained throughout the project life. The facing side to Niagara Parkway of the lay down area shall also have a screen wall erected to downplay the activity within the compound and the public activity along the parkway. For additional reference, refer to Drawing No. MH-6008-00.
Outlet Temporary Facilities:
At the outlet the construction offices will be located adjacent north south portion of the temporary access road. This area is fully fenced and will be approximately 400 m x 50 m. This site will be fully serviced by temporary utilities from Stanley Avenue. In addition Material Yards will be placed throughout the site and will be fully accessible and within the fenced construction area. Their surface will be graded stone and maintained throughout the project life. For additional reference, refer to Drawing No. MH-6009-00.

7.1.2 Roadways

Intake Roadways:
At the intake site a temporary roadway is being constructed to allow access to the site from Portage Road to the construction laydown area and across Niagara Parkway to the construction area at the intake. This will eliminate any need for construction traffic to utilize Niagara Parkway. Roadside ditches will be provided to carry any surface water generated from the roadway into the existing and natural drainage system. A temporary traffic signal will be installed at the intersection of the Access Road and Niagara Parkway to alleviate conflict with construction traffic crossing Niagara Parkway. For additional reference, refer to Drawing No. MH-6008-00.

The existing recreation trail will be relocated to a new location as shown on the drawing to minimize interference of visitors to the area and the construction.

Outlet Roadways:
At the outlet site a new permanent paved access road is being constructed from Stanley Avenue to provide access to the work zones. However only a 180 m section of this road will be built, and beyond this section a temporary roadway is being constructed to provide access to the material stockpiling area and the outlet location. These roadways will be in place until the end of the project and then removed and the area restored to original conditions. Roadside ditches will be provided along these roadways to carry surface drainage from the roadway and other site locations to a detention/settling basin for eventual discharge into the canal system. For additional reference, refer to Drawing No. MH-6009-00.

All roadway design, horizontal and vertical alignments, road widths, surface details, drainage, intersection details, and the like, will comply with highway design requirement appropriate to the class of the road as provided in the above-quoted references.

7.1.3 Fencing
Fencing providing boundary separation and security to the sites will be primarily chain link fences. This will help to eliminate any potential interference between the public and the construction activities. At the intake area, some of the work zones will be fenced off using full height hoardings to afford even better separation and minimize the impact on the appearance of this tourist area.

For additional reference and specific locations, refer to Drawing Nos. MH-6008 and MH 6009.
7.1.4 Stockpiles

During the excavation of the tunnel a large quantity of material primarily rock will be stockpiled between the two power canals as shown on MH-6009. These stockpiles will be between approximately 5 m to 6 m in height with proper and safe side slopes and with the top surface level and graded.

The stockpiles shall be piled in lifts of not more than 300 mm. The stockpile will be setback at a minimum 20 m from the canals and a perimeter trench will be implemented to gather any surface runoff from the stockpiles, collected in a settling basin and discharged through filter cloth into the canal. The ditch surface shall be protected by seeding, and strawbale flow-checks will be provided at 250 m intervals, and before every culvert and intersecting ditch. When the grade of the ditch is steeper than 10%, rockfill check dam will be installed. No stockpile is within 5 m from any part of the tower structures or the location in plan of the overhead transmission lines. A temporary construction pad will be provided for holding materials suspect of contamination. The runoff will be suitably treated prior to discharge. Excavated materials suitable for aggregate production or other uses will be stockpiled separately.

As stated previously, the specifications for stockpiles are located in the Draft Design/Build Agreement and Concept Drawings and also in OPG’s “Management of Excavated Material” dated December 2004 and OPG’s “Management Plan for BTEX” dated December 2004. If the specifications in the Draft Design/Build Agreement and Concept Drawings prevail, then the following will be implemented. A temporary stockpile will be located between the canals and a runoff pond provide for runoff from the excavated materials. This will be used for specific contaminated materials from the tunnel excavation. The runoff will be pumped to the water treatment facility prior to final discharge. The runoff pond and the temporary stockpile will be lined with synthetic material or a minimum of an impervious material to eliminate ground contamination.

If the design is to meet the requirements in OPG’s “Management of Excavated Material” and “Management Plan for BTEX”, then certain rock formations have specific temporary and/or permanent storage requirements based on the information provided by the Reuse of Excavated Materials Committee. The limestones/dolomites above the Rochester Shale formation are to be segregated and stockpiled separately for reuse by the Project. The shales potentially containing BTEX (Rochester, Grimsby and Power Glen formations) are to be isolated permanently in the main disposal area with a perimeter drain leading to the retention pond. The Queenston Shale may be used by the clay/brick industry at a later date and therefore should be stored in the main disposal area separate from the other rock for easy access when required. All other rocks are to be placed in the main disposal area for permanent disposal separately from the other in this area.

The storage area for the excavated material potentially contaminated with BTEX will be approximately 400 m long by 100 m wide and will either have a compacted clay base or impermeable geotextile. Within this area, there will be a 10 m wide buffer area around the perimeter which will contain the drainage ditch/outside berm. The shale will be stockpiled in lifts less than 300 mm and the slope will be no greater than two horizontal to one vertical (2:1). The run-off will be directed towards the retention pond for treatment, if required.
7.1.5 Demolition of the Dewatering Structure

The existing dewatering structure at the PGS Canal is a 45 m long, 6 span reinforced concrete structure, with a 6.7 m wide walking surface on the top. The 5 piers in the water are tall concrete piers with a wide base but tapering up towards the top but all are up to 17 m in height and are sitting on the rock surface of the bottom of the canal, including some embedment into the rock stratum. It is not known whether the structure is manufactured from precast units, but from the information provided, there is definitely a possibility of this and as such it may help to remove the component in convenient chunks instead of breaking into small debris using a concrete breaker.

The 6 span openings are actually gate openings used to close the canal from the main HEP canal for dewatering purposes, though according to information provided to the Proponent, the structure has not been used. OPG provided additional information on the condition of the structure through inspection reports, and suggested that there are damages to certain parts of the structure especially at the abutments and one of the piers (pier 1), and does not use the structure for vehicular traffic anymore.

The method of demolition will be such as to minimize impact on the operation of the PGS and coordination with the timing and duration, as well as the proposed method of removal, will be discussed with OPG and agreed prior to implementation. Sufficient advance notification will be provided to ensure all preparative work be made and all affected personnel informed of the impending work.

The entire superstructure will be removed and the remaining abutment and exposed rock surface stabilized where necessary and where confirmed by the engineer. The pier will be removed up except the last 300 mm which should be intact and firmly fixed into the rock.

Debris catching device will be implemented together with use of barges, at the endorsement of OPG, to minimize concrete debris falling into the water. All sawcutting operations will be controlled and effluent removed using vacuum machine. Large cut reinforced concrete chunk will be removed by lifting from the banks and carting away in truck to designated disposal areas.

7.1.6 Waterline Relocation

During construction an existing waterline will be relocated from the existing PGS dewatering structure prior to the demolition of the structure. The relocation can either be a surface laid/buried waterline laid along the banks of the PGS Canal, and cross the canal at the roadway located outside the PGS station, or on a new utility bridge over the canal at its existing location. Both alternatives will be evaluated, considering cost, timing, impact to other work, etc., and discussed with OPG staff prior to selecting the suitable approach.

The relocated waterline will be constructed to the same standards and details as the existing waterline.

7.1.7 Disposal
The disposal will be conducted in compliance with the Owner’s Mandatory Requirements, section 3.

As stated above, the specifications for stockpiles are located in the Draft Design/Build Agreement and Concept Drawings and also in OPG’s “Management of Excavated Material” dated December 2004 and OPG’s “Management Plan for BTEX” dated December 2004. On-site permanent disposal of excavated material is required for rock from the Rochester, Grimsby and Power Glen formations and rock other than Queenston formation and limestones/dolomites. The Queenston shale will be temporarily stored at the main disposal area and the limestones/dolomites will be reused. The section of the permanent disposal area storing the Rochester, Grimsby and Power Glen formations will be either lined with clay or geotextile to reduce potential soil and groundwater contamination. Runoff will be pumped back across the conveyor bridge to the water treatment facility prior to final discharge. The run off pond will be lined with synthetic material or a minimum of an impervious material to eliminate ground contamination.

Any excavated materials suitable for aggregate production will be stockpiled separately and used where applicable. Any surplus will be removed from the site at the end of the contract. No excavated material or discharge of water prior to treatment will be spilled or placed into any watercourse at the site.

8.0 DESIGN ANALYSIS

8.1 CODES, STANDARDS AND SPECIFICATIONS
The facilities will be designed in compliance with the codes, standards and specifications listed in Section 6 above.

8.2 DESIGN METHODS AND PROCEDURES
The civil works will be designed by using recognized methods and procedures, which include the established and industry standard software in performing in the installation of all work.

9.0 SEQUENCING OF THE WORK
The sequence of construction will be in compliance to the overall schedule provided with the submission. The construction of the temporary facilities will be prior to most activities taking place in support of the tunnel excavation and the intake and outlet structures.

10.0 CONSTRUCTION TECHNIQUES AND EQUIPMENT
The work will be completed utilizing standard construction methods. The use of excavators for grading, trucks for transportation of good and excavated materials when required. A conveyor system will be used to transport excavated materials from the outlet of the tunnel to the temporary and surcharge stockpiles. A water treatment facility will be used on site to treat any and all ground water generated for all construction activity. All equipment and their operation will be in compliance with the EMR and the OMR.
The equipment used for the demolition of the PGS dewatering structure include the use of sawcutting or flame cutting equipment, barges, lifting equipment and debris collecting setup. When necessary, underwater work may be required to retrieve concrete components submerged in the water at the bottom of the canal.

1.0 INTAKE SECTIONAL SERVICE AND OUTLET

1.1 GENERAL

1.1.1 Intake Stop Log

1. One set of sectional service gates (Stop-Logs) with embedded parts and anchor bolts is to be installed inside the intake structure.

2. The embedded part is of two (2) parts design set in the secondary concrete in the intake structure. The load bearing face, seal face and top of the seal beam are type 304 stainless steel, machined after fabrication.

3. Six stop-Logs are required to close off the opening. They are to be lifted in place (or removed) by mobile crane. One (1) follower assembly for handling the stop-log will also be supplied. The stop-logs are to isolate the tunnel from upper Niagara River GIP at the INCW to facilitate tunnel dewatering by OPG.

4. Two (2) 350 mm valves are installed on the top log for use to fill the tunnel.

5. Installation facilities for the intake stop log to enable installation work to be performed above water will include a custom-designed follower structure (as above), as well as a guiding system to permit accurate installation of each intake stop log using a mobile crane. The design of the guiding system will be finalized during the detailed design stage, but the following 2 options will be considered:

   a. Modification of the existing frames for the INCW stop logs to include external top and bottom guiding beams, and provision of new guiding slots in new approach walls and pier extensions to accommodate these modified structure. The details of the existing stop log will be carefully studied to ensure the modified INCW stop logs can function both as a stop log for the INCW gate, as well as a guide for installation of the new tunnel intake stop logs. This method has the advantage of minimizing the storage requirements by OPG.

   b. A specially fabricated steel guide structure complete with walkways to be bolt-connected to the top of the slot in the roof of the intake structure for insertion of the stop logs. This structure will rise above water level to allow workers / OPG employees to control the stop log installation process from the surface.

1.1.2 Outlet Closure Gate, Hoists and Structure

1. One vertical lift, wheeled outlet closure gate with heated embedded parts and anchor bolts will be installed inside the discharge structure. This gate is stop the flow in the tunnel and to prevent admission of water from the canal into the tunnel during dewatering.

2. The embedded parts are of the two-part design that will be set in the secondary concrete. One bolted splice will be installed in the roller path. The roller path is fabricated of hardened stainless steel ASTM A693, Type 630 H1100 and machined after fabrication. The vertical and lintel seal face are type 304 stainless steel, machined after fabrication. Six (6) heaters per gain will be installed down to elevation 163.50 m.
3. The outlet closure gate is a five (5) sections, articulated type, vertical lift gate with four (4) wheels per section. The embedded track is heated with gain heating elements embedded inside the concrete structure.

4. A dual drum wire rope hoist, driven by one 7.5 kW (10 hp) electrical motor is installed to operate this gate. The cable hoist is located inside a hoist bridge and housing mounted on top of two steel tower structures (one stair tower and one maintenance service bay tower). The steel structure is erected above the outlet structure. One air brake is also installed allowing the gate to be lowered, un-powered, under gravity and at regulated speed.

5. One 5-ton hoist and monorail will be supplied and installed in the maintenance tower and hoist bridge.

6. Insulated metal cladding, doors, louvers, windows, translucent panels and associated hardware will be supplied and installed. Roof will be sloped metal deck.

1.1.3 Outlet Stop-Log (Embedded Part Only)

1. One set of Stop-Log embedded parts with anchor bolts (embedded inside the discharge structure) is to be installed downstream of the discharge gate. Stop-Logs will not be supplied for this gate. The embedded parts are installed in case there is a need to stop water entering the tunnel from the canal.

2. The embedded part is of two (2) parts design set in the secondary concrete in the outlet structure. The load bearing face, seal face and top of the seal beam are type 304 stainless steel, machined after fabrication.

1.1.4 Miscellaneous

1. All sealing surfaces and gate roller paths are stainless steel. All three sets of embedded parts are two-part design and to be set in secondary concrete. The load bearing face and seal face, the lintel and the top of the sill beams are of type 304 stainless steel.

2. The outlet closure gate proposed is a 5-part articulated gate. All 5 individual gates are completely shop assembled including seals. The sections will be field connected by link bars and pins. With this arrangement, the top gate can be lifted against downstream pressure by approximately 200 mm to fill the tunnel.

3. The gate structure material will be made of grade 300 and/or 350 WT Cat. 1 structural steel. The wheels are forged 4145 material, crowned and fitted with ‘Timken’ tapered roller bearing. Guide shoes will be installed instead of guide wheels.

4. The outlet gate will be sealed against pressure from either side with rubber seal applied on all four sides. The J seal on the sides and the double stem seal on the lintel are Teflon covered. The seals are bolted on with galvanized steel clamp bars and stainless steel bolts. The bottom of the skin plate and all seal mounting faces are machined. Holes for the axels are bored.

5. The hoist bridge and towers are covered with insulated metal sidings with windows, service door; personnel door, steel stair will be installed on the towers for access to the hoist tower.

6. Access ladders and railing around the outlet gate and stop-log opening will also be installed.

7. Electrical control panels for hoist and heaters will be installed inside the hoist house.
8. The intake and outlet gates will be sandblasted to bare metal and shop painted after fabrication.

9. The hoist house interior will be heated and ventilated per Ontario Ministry of Labour, ASHRAE and NFPA standards and requirements.

10. Adequate lighting will be installed inside the hoist house, stairs, tower, and on the outside walls of the tower structure.

1.2 DESIGN PARAMETERS

1.2.1 General

The design of the intake stop-log and the discharge control gate is in accordance with Section 7 of the Owner’s Mandatory Requirements as part of the Proposal Invitation document.

1.2.2 Basic Design Parameters

Basic design parameter are outlined as follows:

1. Intake Stop-Log

   Tunnel Internal Width = 12.78 m
   Lintel Elevation = 147.03 m
   Sill Elevation = 132.27 m
   Opening Height = 14.55 m
   Normal Maximum Water Level = 171.65 m
   Normal Minimum Water Level = 170.74 m
   200 Years Flood Level = 172.11 m
   PMF = 173.17 m

2. Outlet Closure Gate

   Tunnel Internal Width = 12.78 m
   Lintel Elevation = 164.50 m
   Sill Elevation = 148.62 m
   Opening Height = 15.88 m
   Normal Maximum Water Level = 169.80 m
   Normal Minimum Water Level = 164.20 m
   200 Years Flood Level = 172.11 m
   PMF = 173.17 m
   Surge Water Level at Discharge = 180.00 m

3. Wire Rope Hoist

   Rated Capacity = 1,560 kN
Lifting Speed = 0.16 m/min.
Lowering Speed (Powered) = 0.16 m/min.
Lowering Speed (Un-powered/Fan) = 0.31 m/min.
Motor = 7.5 kW (10 hp), TEFC

Brake = Drum Brake
Reducer = Flender
Rope = 30 mm (1-1/2”) dia. EIPS GALV.
IRWC

Rope Breaking Load = 890.75 kN
(200,000 lb)
Rope Factor of Safety = 9.70 @ Rated Capacity
@ maximum Motor Torque

Drum Diameter = 1219 mm (48”)
Sheave Diameter = 914 mm (36”)

4. Hoist Control

One control panel will be supplied and installed inside the hoist housing. Controls include:

- Raised/Stop/Lower and Emergency Lower Push Button
- One Local/Remote/Maintenance selector switch
- Pilot light for Power On; Gate Raising; Gate Lowering; Gate Close; Gate Fully Open
- Limit Switches for Lower Position (rotary type); Upper Limit; Dogging Position; Anti-Creep;
- Slack Rope and Power Over-Travel Switches
1.3 INSTALLATION AND COMMISSIONING

1.3.1 Embedded Parts

1. Three (3) sets of embedded parts with anchor bolts will be shipped to site for installation in the intake and discharge concrete structure. The installation will be the responsibility of the gate manufacturer and supplier.

2. The gate supplier will also apply secondary concrete ensuring proper alignment of the embedded parts.

1.3.2 Intake Stop-Log

The Stop-Log sections will be dry tested. They will be lifted in place and removed under dry condition. Upon completion of the construction and after the tunnel is filled and the gate is submerged, the gate manufacturer will assist in lifting the Stop-Log sections, removing them from the inlet structure. The gate supplier will also assist to install the slot cover after removing the Stop-Log.

1.3.3 Outlet Closure Gate

The outlet closure gate, along with the hoist structure; housing; access ladders; railing and heater and hoist controls will be installed by the gate supplier. The gate supplier will also commission the gate hoist ensuring proper operations of the closure gate.

1.4 SHOP DRAWINGS AND O/M MANUALS

1.4.1 Shop Drawings

Manufacturer’s Shop Drawings indicating details of the gate design and construction will be provided by the gate manufacturer and submitted to OPG for review, acceptance and records. Prior to the completion of the project, Operating and Maintenance manuals will be submitted to OPG for records.

1.4.2 Codes and Standards

2.2  CONSTRUCTION/SEQUENCING OF THE WORK ................... 3
1.0 ELECTRICAL SERVICES

1.1 POWER SUPPLY

1.1.1 Supply To Outlet Structure – Permanent Service (Hoist Tower)

Power Sources

1. Power to the site can be provided from one of the existing overhead lines installed in proximity of the site. One of the lines is a 27.6 kV circuit assumed to have sufficient capacity to carry the permanent electrical load of the outlet shaft structure.

2. The line referred to runs in a north-south direction, approx. 1.5 km west of the site of the proposed outlet shaft.

Transmission

1. Power needs to be brought to the site of the proposed outlet shaft via a three-phase pole line, approximately 1.5 km long. Spacing of the poles is anticipated to be approx. 60 m, resulting in a total number of approximately 26 poles. Connection of the spur line to the 27.6 kV supply line shall be carried out by OPG/Hydro One.

Termination

It is proposed that a pad-mounted transformer be provided at the site of the outlet shaft. The transformer shall be rated 225 kVA, 27.6 kV – 600/347V, 3-phase. Transformer’s feeders shall as follows:

Primary:

- 3 fuse cut-outs at the dip pole
- 3 lightning arresters, pole mounted
- 3 cable terminations
- 3-#1 AWG, 28 kV, concentric neutral cables in 3-100 mm PVC conduits – cca. 25 m

Secondary:

- 4-350 MCM RW90, 1000 V insulation, in 100 mm rigid PVC conduit, cca. 10 m

1.1.2 Supply To Tunnel Outlet Shaft Portal – Construction Power Service

Power Source

It is proposed that the construction power service be derived from the 110 kV line available at the south of the site. Approximate location of connection point is 500 m south-east of the site of the outlet shaft. Given the proximity to the transformer station where the line originates, it is assumed that ample capacity exists in this feeder to provide for the construction power.
requirements, estimated at 13.3 MW. This shall be verified by the Contractor at the commencement of the construction.

**Termination**

An on site (temporary) substation shall be constructed and shall contain the following components:

- 2-7.5 MVA, 110 kV-4.16/2.4 kV power transformers, outdoor, pad mounted
- Supporting structure for incoming protection & metering equipment
- 5 kV Class secondary switchgear, c/w:
  - 2 main (incoming) switches
  - 1 tie switch
  - 6 feeder switches (tunnelling equipment & support systems + site support/services systems)
- 1-2000 kVA, 4.16 kV-600/347 V pad mounted transformer
- 600/347 V, 2500A low voltage switchgear, outdoor type (or installed in a container/shed), c/w:
  - 2500 a main breaker
  - 6-1600 A/800 AT breakers (for WTP, site office/store, crane, cooling water system etc.)

**2.0 MECHANICAL SERVICES**

**2.1 HEATING AND VENTILATION (HOIST TOWER)**

**2.1.1 Heating**

1. Heating in the form of electric baseboard heaters and wall mounted electric cabinet heaters with built-in thermostatic control will be installed inside the outlet closure gate hoist tower and housing.

2. The heating system will be designed to maintain the indoor temperature at 10°C (50°F) during the heating seasons. This feature is in compliance with the OBC requirements, and to prevent freezing inside the hoist house. Heating will also prevent condensation on electrical and mechanical equipment and ensuring reliable operations of the electrical and mechanical equipment.

**2.1.2 Ventilation**

Gravity ventilation in the form of strategically located, and appropriately sized louvers will be installed in the hoist house. Sufficient air is designed to circulate through the hoist house maintaining the indoor air temperature at not higher than 6°C (10°F) above the outdoor air temperature in the cooling seasons. The feature is to avoid possible accumulation of foul gas and/or odour.

**2.1.3 Design Conditions**

Indoor Conditions:

- Heating Seasons 10°C (50°F) Maximum
• Cooling Seasons  6°C  (10°F) Higher than Outdoor Air Temperature

Ambient (Outdoor) Conditions:
• Heating Seasons  -5°C  (23°F)  ASHRAE 99.6%
• Cooling Seasons  28°C  (82°F) DB  ASHRAE 0.4%
                 21°C  (70°F)  MWB

2.1.4 Plumbing And Drainage

1. Provision is made for the installation of one washroom inside the hoist house.
2. The facility will include one water closet, one lavatory and one electric hot water heater.
3. Domestic water pipe shall be installed connecting the washroom to a nearest Municipal domestic water main. We will also install sanitary drain line connecting the washroom to a nearest Municipal sanitary main.
4. Vent stack and trap-seal-primer will be installed preventing sewer gas from migrating into the washroom.

2.1.5 Code And Standards

1. OBC - Ontario Building Code
2. ASHRAE - American Society of Heating, Refrigerating and Air Conditioning Engineers
3. AMCA – Air Movement and Control Association International
4. ANSI – American National Standards Institute
5. AWWA – American Water Works Association
6. CSA – Canadian Standards Association
7. NFPA – National Fire Protection Association
8. SMACNA – Sheet Metal and Air Conditioning Contractors’ National Association

2.2 CONSTRUCTION/SEQUENCING OF THE WORK

The construction will be undertaken using standard construction techniques and standards for the industry. The sequencing will be established to support the overall scheduling of the project.

1 GENERAL

1.1 General Project Overview

Ontario Power Generation (OPG) is implementing the Niagara Tunnel Facility Project aiming to bring water from the Niagara River to an existing storage reservoir. The key elements of the project are:

- Intake Structure and Channel
  - approx. 200 m long
  - approx. 20 m wide
  - up to 30 m deep

- Delivery Tunnel
  - approx. 10.4 km long
  - approx. 12 m internal diameter

- Outlet Structure and Canal
  - approx. 400 m long
  - approx. 20 m wide
  - up to 35 m deep

In addition a dewatering system consisting of 5 vertical shafts with approx. 0.8 m internal diameter, dewatering pipe and culvert is planned. The tunnel shall also be monitored by piezometers and extensometers during operation. Gates are to be situated at the Intake and Outlet. Also new guiding walls are required in the river upstream of the Intake.

It is planned to transfer 500 m³/s of water with the tunnel facility to the reservoir. The operational time of the facility will be 90 years. It shall be capable of being opened and closed as required. Also dewatering of the facility shall be feasible at unspecified intervals to facilitate maintenance. The intake and outlet structures of the Niagara Tunnel facility are to be located at fixed points. A corridor is provided in plan for the New Diversion Tunnel (No.3), which basically runs parallel with the two existing Diversion Tunnels No. 1 and 2. One other constraint is for the New Diversion Tunnel (No. 3), that subject to the Environmental Assessment Approval no permission is currently given for crossing through the buried St. David’s Gorge. The alignment grade for the tunnel is to be selected such, that crossing under the gorge is realized. At least 100 m of ground overburden have to be considered as a result of such deep alignment. In addition regional swelling and squeezing phenomena and highly aggressive saline groundwater have to be taken into account for implementation of all structures associated with the project.
1.2 Scope

The outline design basis and method statement covers primarily aspects of tunnel design (hydraulic design, geotechnical design, civil design, structural design etc.) and the design of associated structures, which are

- Diversion Tunnel
- Intake Structure
- Outlet Structure
- Outlet Canal
- Dewatering Shafts, Pipe and Culvert
- Permanent Instrumentation (i.e. tunnel piezometers and extensometers)

Design basis and method statements associated with

- accelerating walls at the intake
- temporary facilities
- roads and parking areas
- rail road trackage and sidings at the outlet area
- fencing, gates and barriers
- stockpiles and water treatment facilities
- cofferdams and temporary docks
- demolition and disposal

are covered elsewhere in the Proposal.

The following aspects of design and construction shall be covered with this document:

- layout of works
- design approach
- codes and standards
- specifications
- construction techniques

Construction aspects associated with

- equipment
- sequencing of the Work and
- layout of construction facilities

are covered elsewhere in the Proposal.

Emphasis is given, that the design basis and construction methodology specified herein is organized such to address the Owner’s Mandatory Requirements.
1.3 Preliminary Design and Construction Considerations for the Diversion Tunnel

1.3.1 Diversion Tunnel Alignment

The Proposal design follows the concept alignment in principle. Only below the buried St’ David’s Gorge, the alignment is slightly relocated to the north-west to gain maximum rock cover, which is predicted close to the location of geotechnical borehole SD-8. Horizontal and vertical curvature is arranged such to maintain a min. 1000 m radius for to facilitate muck transportation by conveyor belt systems. In addition the alignment close to the existing outlet structure is moved away from underneath the existing Delivery Tunnel No. 1, to facilitate the drilling of the borehole for tunnel piezometers.

The overall depth of the tunnel has been slightly reduced as compared to the concept design. The inclination of fall and raise of the grade near the outlet and intake of the facility is arranged slightly shallower as in the concept design. The dewatering structure has also been moved further away from the buried St’ David’s gorge as compared to the concept design. A potential fourth Diversion Tunnel may be arranged in parallel to the proposed alignment route.

1.3.2 Diversion Tunnel Lining

Originally two lining alternatives for the Diversion Tunnel have been investigated by the Proponent:

- Single shell lining with precast concrete segments
- Double shell lining with an initial lining of shotcrete, ribs and rock bolts and a final lining of cast in place concrete. Both linings being separated by a waterproofing membrane system.

Although easier to apply in combination with a Tunnel Boring Machine (TBM), the single shell lining alternative has been abandoned for the following reasons:

- The surface roughness of precast segments ($K_s = 75 – 80$) is inferior to cast in place concrete ($K_s = 85 – 90$) according to Strickler (see chapter 2.3).
- Although compressible annular grouting mortar is available to compensate deformations resulting from rock squeeze, it is not possible to hold the operational internal water pressure in segmental lining rings. Water could escape through segment joints at pressures up to 14 bar and could adversely affect the rock of formations, which are sensitive to water. High swelling pressures or even worse, erosion of ground around the tunnel would be the undesirable result.
- It cannot be guaranteed, that uniform grouting of the annulus around the segmental lining ring is achieved, since rocks falling from behind the shield of the TBM into the
annular gap may cause shadowing and voids when grout is injected. No controlled prestress of the segmental lining ring is possible.

- Many lining segments can be damaged during fabrication, transportation and erection. Either an economical loss or restrictions in durability are the result of rejected segments or massive repairwork.

For such reasons the double shell lining option is the preferred proposal. The cast in place lining solution provides also the following advantages:

- Flexibility with respect to internal diameter. With an expandable steel formwork, sections of minimum rock support requirements may be utilized to adjust the tunnel diameter to provide maximum flow rates.

- The arrangement of a waterproofing membrane between initial lining and final lining prevents the aggressive groundwater to get in contact with the final lining concrete.

- The installation of a comprehensive interface grouting system enables to compress the final concrete lining such, that internal water pressure is held without the lining concrete being cracked in tension. Hence the requirement of steel reinforcement can be eliminated for the final lining. The tunnel structure is tightly embedded into the rock and the enormous interactive load bearing capacity of ground and structure is consequently mobilized.

### 1.4 Durability Aspects

#### 1.4.1 Service Life and Constraints

The operational design life for the Niagara Tunnel Facility Project shall be 90 years. No outage of the Diversion Tunnel shall occur during such period. The tunnel lining has to resist:

- acid and sulphate attack from an unfavourable environment
- high internal and external pressures from ground and water
- the abrasive action of water, ice and debris within this operational time period.

#### 1.4.2 Design and Construction for 90 Years Service Life

In vision of the extraordinary challenge to meet the specified requirements for a service life of 90 years, the following design aspects have been determined to serve the purpose:

- Construction of a double shell lining instead of a single shell lining. The initial rock support is timely separated from final lining erection, which improves the quality of the final structure in total.
- Separation of the final lining from the aggressive environment by a waterproofing membrane system. The waterproofing system is vacuum tested to ensure reliable performance. Any exchange of water or chloride between inside and outside of the tunnel is inhibited.

- Tight connection between final structure and the surrounding rock mass to mobilize the load bearing capacity of the rock for the 90 year operation requirement. By no means it shall be allowed that rocks and debris is washed out and voids behind the lining are created. The tight connection is achieved by contact grouting, interface grouting and cavity grouting where required.

- Prestressing of the final lining to create a compressed concrete support ring, which is able to sustain internal waterpressure without steel reinforcement being required. The risk of corrosion for reinforcement within the 90 years design life is such eliminated. The prestressing of the tunnel with interface grouting takes the rock mass surrounding the tunnel close to its original stress state and reduces or eliminates adverse time dependent deformations of the rock mass.

- Design of the concrete structures against uplift uses the self weight of the structure only. Long term rock deformations, which cannot be controlled by stress resistance of the concrete structure are compensated without exerting additional load by a compressible material placed between structure and rock. Overstressing of the concrete during the 90 years of specified operation is therefore avoided.

- In general materials shall be used, which are
  -- recorded over a design life of 90 years (i.e. concrete, grout etc.)
  -- tested to serve over a design life of 90 years (i.e. membrane materials, coated steel etc.)
  -- easy to maintain or exchange if necessary (i.e. sill gates, tunnel piezometers, etc.)

1.4.3 Comprehensive Durability Testing

The testing of materials will be phased in

- testing by the manufacturer against specified performance criteria (base product quality)
- testing on site against particular application criteria (applied product quality)
- testing of sections of the completed structure or product where possible (final product quality).

Hence a high degree of quality assurance will be ensured to achieve the specified product quality required for the 90 years design life of the facility.
2 HYDRAULIC DESIGN

2.1 Water Surface Elevations

Water surface elevations to be prepared are based on NAD 83 (following the 1973 International Niagara Board of Control Directive).

2.2 Hydraulic Design Approach

The hydraulic conveyance system extends from the intake structure at the GIP to the outlet water level gauge in the outlet canal and includes the intake channel, the intake structure, the tunnel, the outlet structure and the outlet canal to the point immediately upstream from the transition at the junction with the PGS channel. The discharge of the conveyance system will be measured and calibrated considering the head of energy losses between the upstream and downstream level gauges.

The tunnel conveyance system will be designed, detailed and constructed to provide the optimum hydraulic efficiency. This is valid also for the construction of the inlet- and outlet structure and for the outlet canal.

The tunnel will be capable of delivering a GFA with the hydraulic head and energy grade design level defined in Appendix 1.1(aa) to the Design/Build Agreement considering the hydraulic conveyance system defined in Section 8.2(1).

Transient load analysis has been performed based on powered and unpowered closure rates for outlet gate and appropriate intake and outlet water levels. The analysis is provided in chapter 2.4 of this document.

Loads determined from the transient load analysis will be used for input into the design of the outlet gate and structures and tunnel liner. The outlet surge shaft will be sized to limit the transient load while retaining the upsurge water level within the confines of the shaft.

2.3 Steady Flow Conditions

2.3.1 References

For calculation of the steady flow conditions the following literature has been used:

[2.2] Gerhard Seeber: Druckstollen und Druckschächte, 1999, Georg Thieme Verlag
[2.3] Schneider: Bautabellen für Ingenieure, 11. Auflage, 1994, Werner Verlag
[2.4] Bemessungsblätter (tables for calculation) by TIWAG (Tyrolean Hydro Power Company)
2.3.2 Diversion Tunnel

2.3.2.1 Selection of the formula for calculation of the flow losses in the tunnel section

Acc. to [2.2], the flow losses in pressure tunnels are mostly calculated using the formula of Strickler, but if it is in the range of application, the calculations would be more exactly using the formula of Prandtl-Colebrook.

Using the basis data for the tunnel of the Niagara project, it can be shown, that the formula of Prandtl-Colebrook reached its limit and gives wrongly sometimes negative roughness coefficients.

Hence the Strickler-Formula is better used for calculations of flow losses in such cases.

Therefore the formula of Strickler has been applied for the calculation of flow losses in the Diversion Tunnel.

2.3.2.2 Roughness coefficients as given in the literature

The literature provides the following coefficients for the Strickler formula for tunnels with final concrete lining:

a) In [2.1] Table 17, page 281, coefficients acc. to Strickler formula:

- Geschliffener Zementputz größter Glätte $K = 100$
  (polished cement liner, maximum smoothness)
- Betonstollen und Eisenbetondruckrohrleitungen, glatt, sehr sorgfältige Ausführung, unversehrter Glattputz $K = 85$ bis $95$
  (concrete lined tunnels and concrete pressure pipes, smooth, very thorough finish)
- Betonstollen von weniger sorgfältiger Ausführung $k = 70$ bis $80$
  (concrete lined tunnel, less thorough finish)

b) In [2.2] page 22, coefficients acc. to Strickler formula:

- Spritzbeton, je nach Dicke und Ausbruchsart, mechanisch $Kst = 50$ bis $65$
  (shotcrete, depending on thickness and excavation type, mechan.)
- Schalbeton (Stahlschalung) $Kst = 80$ bis $90$
  (concrete with steel formwork)
- Panzerung mit Anstrich $Kst = 90$ bis $110$
  (steel lining with painting)

c) In [2.3], page 13.21, table Manning-Strickler coefficients:

- Beton: Druckstollen, sorgfältige Ausführung: $Kst = 85$ bis $95$
  (pressure tunnel with concrete inner lining, thorough finish)
d) In [2.4] Calculation diagrams of the TIWAG (Tyrolean Hydro Power Company)

- Reibungsverluste für Kreisprofile nach Strickler, \( K_s = 85 \) (Betonauskleidung, Stollen)  
  (Friction losses for tunnels, concrete inner lining)

- Reibungsverluste für Kreisprofile nach Strickler, \( K_s = 100 \) (Stahlauskleidung, Schächte)  
  (Friction losses for shafts, steel lining)

e) In [2.5], table 5-6, values of the roughness coefficient \( n \):

- Concrete, “finished” \(^n\) between 0.011 and 0.014, typical = 0.014  
  \(^n\) means \(1/K_{st}\), therefore the coefficient \( K_{st} \) is between 71 and 91, typical 83

### 2.3.2.3 Roughness coefficients used for calculation

Summary for the coefficients as given in the literature

<table>
<thead>
<tr>
<th>Literature</th>
<th>Description</th>
<th>Roughness Coefficient</th>
</tr>
</thead>
<tbody>
<tr>
<td>[2.1]</td>
<td>Tunnel, concrete inner lining, smooth, very thorough finish</td>
<td>( K_{st} = 85 ) to 95</td>
</tr>
<tr>
<td>[2.2]</td>
<td>Pressure tunnel with steel formwork</td>
<td>( K_{st} = 80 ) to 90</td>
</tr>
<tr>
<td>[2.3]</td>
<td>Pressure tunnel with concrete lining, thorough finish</td>
<td>( K_{st} = 85 ) to 95</td>
</tr>
<tr>
<td>[2.4]</td>
<td>Tunnel with concrete lining</td>
<td>( K_{st} = 85 )</td>
</tr>
<tr>
<td>[2.5]</td>
<td>Concrete “finished”</td>
<td>( K_{st} = 71 ) to 91, typical = 83</td>
</tr>
</tbody>
</table>

It is assumed, that according to these coefficients (given in the literature) the Contractor will certainly achieve a roughness coefficient of \( K_{st} = 85 \) in the concrete lined Diversion Tunnel when using a steel formwork with a thorough finish. Depending on other parameters like the length of the formwork section and the thorough execution of the transition from one formwork section to the other, perhaps a higher coefficient could be achieved (range up to \( K_{st} = 90 \))

But as a conservative approach, the roughness coefficient of \( K_{st} = 85 \) is applied to the tunnel section.

### 2.3.2.4 Transition at change of thickness of inner lining

According to [2.1] the losses for a gradual dilatation into a larger cross section can be calculated as:

\[ z = c \times (1 - (F_2/F_1))^2 \]

Whereas \( c \) = Correction factor (at 8° degree: 0.15 to 0.20)

and \( F_1 \) and \( F_2 \) is the area of cross section before and after the dilatation.

Example for a dilatation of the inner ling of 0.2m:
• D1 = 12.00m, F1 = 113.1m²
• D2 = 12.40m, F2 = 120.8m²
• Flow assumed 500 m³/s, therefore at F2 flow velocity v = 4.14 m/s
• c = 0.20

Result: \( z = 0.0009 \) and the flow losses \( hv = 0.0008 \text{m}, \) which is negligible.

For a gradual dilatation into a smaller cross section the flow losses are negligible (acc. to [2.1])

Conclusion: If the dilatation is gradually and slow (e.g. does not exceed 8°), the losses at the transition can be neglected.

2.3.3 Channels

2.3.3.1 Formula for calculation of the flow losses in the intake channel and the outlet canal

For the calculation of the hydraulics of the channel the formula of Strickler has been used.

2.3.3.2 Roughness coefficients given in the literature

a) In [2.5], page 110, table 5-6, the roughness coefficients “n” (which is 1/Kst) are provided for:

Channel, Rock cuts:
• smooth and uniform: “n” = minimum 0.025, typical 0.035, maximum 0.04
• Jagged and irregular: “n” = minimum 0.035, typical 0.040, maximum 0.05

This results in Kst-coefficient for the Strickler formula of:
• smooth and uniform: Kst = minimum 25, typical 28.6, maximum 40
• Jagged and irregular: Kst = minimum 20, typical 25, maximum 28.6

b) In [2.3], page 13.21, the following roughness coefficients are listed for rock excavations:

• Rough excavation: Kst = 15 to 20
• Medium rough excavation: Kst = 25 to 30
• Rock excavation, well cut or bored: Kst = 45 to 50

2.3.3.3 Roughness coefficients used for calculation

It is assume that the excavation will be smooth and uniform and with respect to [2.3] considered a well prepared “medium rough excavation”

Therefore we assume that the excavation for the outlet canal can be modelled with a coefficient of Kst = 30 acc. to the Strickler formula.
The flow at the intake channel is actually 3-dimensional, which is not considered by the formula of Strickler. Therefore a reduced coefficient of $K_{st} = 25$ (instead of $K_{st} = 30$) is applied at the intake channel to consider possible additional losses in this section.

(Flow losses are 4 cm at $K_{st} = 30$ compared to 6 cm for $K_{st} = 25$ at the intake channel).

2.3.4 Intake- and Outlet Structure

2.3.4.1 Formula for calculation of the flow losses

For the calculation of hydraulics in the intake- and outlet structures, again the formula of Strickler is used. The calculations have been performed on vertical cross sections.

2.3.4.2 Roughness coefficients presented in the literature

a) In [2.1], page 281, table 17, the following roughness coefficients are presented for concrete.

“Smooth and undamaged liner, smooth concrete with high content of cement: $K_{st} = 80$”

b) In [2.3], page 13.21, the following roughness coefficients are listed for concrete:

- Concrete, wood formwork: $K_{st} = 65$ to 70
- Concrete, steel formwork: $K_{st} = 90$ to 100

2.3.4.3 Roughness coefficients used for calculation

The assumption is, that the surface of the structures can be cast smoothly although some of the surfaces are not flat but curved.

Therefore we assume that the surfaces of the intake- and outlet structures can be modeled with a coefficient of $K_{st} = 80$ for the Strickler formula.

2.3.5 Summary of Roughness Coefficients

The formula of Strickler has been used for the calculation of the flow losses for steady flow conditions for the entire water transfer facility. The calculations acc. to Strickler are carried out using vertical cross sections. It has to be noted, that with the used mathematical model (based on the Strickler formula) 3D- flow and associated losses are not considered. However the calculation results are still suitable to represent the flow of water, since the losses, which are not considered will be comparatively small and therefore negligible.

The following roughness coefficients are used:

- Intake Channel: $K_{st} = 25$
- Intake Structure: $K_{st} = 80$
- Diversion Tunnel: $K_{st} = 85$
Outlet Structure: \( K_{st} = 80 \)
Outlet Channel: \( K_{st} = 30 \)

Since the transition between different thicknesses of final lining is gradually and slow (e.g. does not exceed \( 8^\circ \) of opening angle between two cross sections of different size), the flow losses due to the transition are neglected in the tunnel section.

2.3.6 Hydraulic Analysis for Steady Flow Conditions For the Entire Conveyance System

The entire conveyance system has been calculated by computer using the formula of Strickler and the roughness coefficients as stated before.

The base data for the steady flow conditions are:
- \( H_{ref} \) (as defined in Appendix 1.1(aa) to the Design/Build Agreement) = 5.60 m.
- The layout of the conveyance system is defined in the Proposal Drawings.
- Roughness as defined in the previous chapters.

The result of the calculations is a discharge of 502 m\(^3\)/s for the Proposal.

The printout of the computer calculation results is included in the Appendix 2.1.

2.4 Unsteady Flow Conditions (Transient Load Analysis)

2.4.1 General

For unsteady flow conditions in the conveyance system the operation of the gate in the outlet structure has to be investigated. For lowering the gate two load cases have to be investigated: the powered lowering (max. speed 0.16 m/min) and unpowered lowering (max. speed 0.31 m/min). Additionally the load case for raising the gate (max. speed 0.16 m/min) has been investigated.

To cover also unfavourable load cases, the maximum discharge for calculation of the unsteady flow conditions was assumed with 550 m\(^3\)/s.

The aim of the calculations is to prove that the assumed lowering and raising times and the closing laws of the gate are suitable to retain the upsurge water level within the confines of the surge shaft at the outlet structure.

It has to be noted that for the calculation for the unsteady flow, the closing characteristics for the gate has been assumed. In the detailed design phase the unsteady flow calculations have to be repeated using the manufacturer’s real characteristics of the gate which will be installed.
2.4.2 Computation Method, Software

The transient analyses have been performed using computer software developed by ILF, the efficiency of which has been proven in numerous projects. Large water transmission systems, hydropower stations as well as crude oil and products pipelines have been studied. The computer software is based on the “method of characteristics”.

2.4.3 Computation Procedure

In general the following procedure is adopted:

Starting from a pre-defined steady state condition, the hydraulic behaviour of the system is calculated reviewing different events which might disturb the steady state condition.

Possible disturbances might comprise:

- Scheduled or unscheduled gate valve closure during operation
- Scheduled system shut-down
- Scheduled system start-up
- etc.

The load cases selected for this report were those which result in maximum or minimum pressures in the system, or show special behaviour of the system under transient conditions.

The computations always comprise the entire hydraulically active system.

2.4.4 Mathematical Model

The hydraulically active system has been converted into a numerical (= mathematical) model which conduces as input model for the computer software. The mathematical model includes respectively describes all necessary system parameters like tunnel diameter distribution, liquid properties, levels and stations, e.g. as well as characteristics for all hydraulic relevant equipment like surge shafts, valves, etc.

2.4.5 Presentation of Computation Results

The computation results are presented by:

- Computer Prints, Hydraulic Profiles, “Situation at Time”
  The printouts show the actual flow rate, the actual minimum and maximum pressures for the system nodes and the actual status of equipment at a precise time point.
- Computer Prints, “History of Events”
  The printouts show the development of pre-selected values during the calculation
2.4.6 Load case 1: "Gate Hoist Lowering Powered (max. speed = 0.16 m/min)"

2.4.6.1 Basic Data

The following basic data have been used:

- Maximum speed of lowering: 0.16 m/min
- Discharge at start of the calculations: 550 m³/s
- Roughness of tunnel lining: \( k_s = 0.028 \text{ mm} \) (acc. to Prandtl Colebrook)
  
  \( \text{corresp. } K = 85 \text{ acc. to Strickler at the given conditions} \)
- Valve type: gate valve
- Valve inside diameter: 15.88 m
- Valve design pressure: ASME 150

2.4.6.2 Result

For to retain the upsurge water level within the confines of the surge shaft at the outlet structure a two-speed closure has to be considered.

- Closing speed 1: 5955 sec
- Point of speed change: 12% remaining open position
- Closing speed 2: 38830 sec
- Closing time 1 (100% to 12%) 5240.4 sec
- Closing time 2 (12% to 0%) 4659.6 sec
- Total closing time (100% to 0%) 9900 sec = 165 min
- Max. water level in the surge shaft: 179.52 m
- Min. water level in the surge shaft: 167.49 m

2.4.9 Computation Results

The above performed hydraulic transient computations lead to the following closing characteristics for the tunnel system endpoint gate valve:

- Total closing time gate valve, powered (max. speed = 0.16 m/min) 165.0 min
- Total closing time gate valve, unpowered (max. speed = 0.31 m/min) 122.7 min
- Total raising time gate valve (max. speed = 0.16 m/min) 99.3 min

As already mentioned above, the computations of these three load cases are strongly influenced by the gate valve zeta v, Kv or Cv characteristics. For the present computations only standard characteristics which provide conservative results have been used. During detail design phase the gate valve manufacturer has to supply the real characteristics and the computations have to be repeated accordingly.

In addition it has to be stated, that during the closing process standard gate valves are hydraulically not active until they reach the set point of approx. 15 to 10 % remaining open position (depends on type and construction of valve). During the first period up to approx. 85 % closure of the gate, when the valve is hydraulically inactive and no pressure surges will be produced, the valve could be operated at a faster closing speed. This fact would minimize the total closing time of the gate. To confirm this statement the mechanical boundary conditions, like size and possible speed of gate actuators, etc., have to be considered as well.
3 GEOTECHNICAL DESIGN AND CIVIL DESIGN

3.1 Survey

3.1.1 Survey Datum

Drawings and survey relevant data is prepared in NAD North American Datum (NAD83).

3.2 Civil Design Diversion Tunnel

3.2.1 General

The tunnel dimension, the surfaces of linings and lining transitions are designed to deliver the anticipated GFA. The tunnel is capable of being dewatered within a specified time of 3 weeks and the tunnel lining are designed to resisting all internal and external loads that are anticipated during the service life of the Diversion Tunnel.

The final lining concrete is protected by a waterproofing membrane system from the highly aggressive groundwater attack as identified in the GBR.

3.2.2 Tunnel Alignment

The alignment of the Proposal is described in chapter 1.3.1. It shall be noted, that the alignment of the tunnel satisfies the following requirements:

(a) the submerged intake of the tunnel is located beneath Gate 1 of the INCW at the location N 4 770 373.110 and E 658 118.470. The tunnel axis starts with a straight line in plan perpendicular to the centre line of the bridge as indicated on the Concept Drawings.

(b) the outlet structure of the tunnel is located on the northwest side of the SAB2 Canal as indicated on the Concept Drawings. The Diversion Tunnel ends at the location N 4 778 230.990 and E 657 595.510.

(c) the horizontal alignment of the tunnel does remain within the subsurface right of way for the existing tunnels as indicated on the Concept Drawings

(d) the tunnel alignment does allow a future construction of a tunnel similar to the concept design with an intake beneath Gate 4 of the INCW and an outlet structure parallel and located south of the new tunnel outlet structure. The tunnel alignment indicated in the Proposal does allow a future construction of a tunnel also in parallel to the proposed Diversion Tunnel.

(e) the tunnel alignment does not cause severe stresses and strains to the lining of the existing tunnels or to the Toronto Power Generation Station building, wheel pit and dewatering tunnels as determined by numerical analyses. The alignment of the Proposal is crossing the wheel pit and the existing tunnels at a depth, where no influence on the
existing structures is to be expected.

(f) a dewatering station is provided at the low point of the tunnel. The shafts are located on the Owner’s land approx. 50 m east of the eastern rim of the buried St. David’s Gorge.

3.2.3 Tunnel Lining Design

1 The tunnel lining consists of

(a) initial shotcrete lining – depending on the excavation and support type applicable for a particular section of tunnel, shotcrete, steel wire mesh, steel ribs and rock dowels are installed for temporary support of ground within adequate time after excavation.

(b) final cast in place concrete lining – which will be capable of accepting all permanent loads.

(c) waterproofing membrane system – which prevents seepage between inside and outside of the Diversion Tunnel and acts as a suitable corrosion protection for the final lining

(d) high pressure interface grouting system – which is designed to prestress the final concrete lining and the surrounding rock such, that no reinforcement of the final concrete lining is required.

Hence the final tunnel lining is watertight under normal operating conditions, rock swelling effects do not occur and the highly corrosive environment that exists along the tunnel alignment does not affect the final tunnel lining.

3.2.4 Tunnel Excavation and Construction

The tunnel will be excavated by means of a TBM starting from the outlet end of the tunnel. The TBM is erected in the flat section of the Outlet canal, pushed into the launch chamber where tunnel boring commences.

At the intake, which is excavated by the time, the TBM arrives, the TBM is dismantled when leaving the tunnel and taken out of the construction pit in parts.

The use of drill and blast method of excavation will be limited to:

(a) intake structure
(b) intake channel
(c) outlet structure and
(d) outlet canal.
Two short sections of mined tunnel will also be excavated by drill and blast. These tunnel sections are adjacent to the intake and outlet structures and 12 m and 20 m long respectively. The mined tunnel section at the outlet is used for TBM launch.

The dewatering shafts and tunnel piezometer holes will be drilled from the ground surface by standard boring techniques.

### 3.2.5 Tunnel Lining Installation

The tunnel initial lining will be installed in due time after excavation from behind the cutter head and from the working platform of the TBM. It consists of steel wire mesh, rock dowels, steel ribs and shotcrete as defined by the applicable support type. The initial lining is installed for the protection of personnel working in the tunnel and used for rock support and drainage of seepage water until the final lining is in place.

Within the TBM backup precast concrete invert segments are placed for to facilitate supply of the TBM advance. The invert segments are placed on a waterproofing membrane layer, which is adequately protected and they are grouted with mortar to be held in place properly. The invert segments serve as a foundation for the formwork of the cast in place final lining and are incorporated in the final lining.

Before the final lining is installed, the preset rings for interface grouting and a waterproofing membrane system consisting of regulating shotcrete, waterproofing membrane and plastic-backed geotextile fleece are fixed to the tunnel surface.

A steel shutter is used to pour the final lining consisting of cast in place concrete in approx. 12 m long sections. Adjustable formwork segments allow to vary the internal diameter of the Diversion Tunnel. Hence, depending on the internal and final lining thickness, maximum flow rates can be accommodated for water transfer. Changes of the internal tunnel diameter as a result of variable lining thickness and adjustable formwork are smoothened by a short transition section to minimize flow losses.

Eventually the final lining of cast in place concrete is prestressed by interface grouting applied between the initial lining and the waterproofing membrane system. The compressed final lining concrete resists the internal water pressure without cracking. The method has been successfully applied in pressure tunnels and shafts of hydro power schemes before (Appendix 3.4).

### 3.3 Geotechnical Design Approach

#### 3.3.1 Introduction

Tunnel design is governed by the fact that “Rock masses are so variable in nature that the chance for ever finding a common set of parameters and a common set of constitutive
equations valid for all rock masses is quite remote.” [3.15]. Therefore it has to be taken into account that, prior to tunnelling, any design represents a prediction which is either (a) verified on site in the event that all design assumptions are confirmed or (b) adjusted in situ to suit actual conditions. Figure 3.1 indicates the design approach which has been adopted.

The design procedure is based on the guideline for the geomechanical design of underground structures [3.9] developed by the Austrian Society for Geomechanics. The first step of the design procedure is to establish geological data in those sections along the tunnel profile with consistent characteristics and then to summarize the geological series with similar mechanical properties. Further, the boundary conditions such as virgin stresses, size, shape and orientation of the opening have to be taken into account in order to establish a possible failure mechanism, thereby establishing the behaviour of the opening. Different failure mechanisms require different support measures as well as models of analysis to design the support measures. In order to simplify procedures at the site, support types are established which are applicable for the various types of behaviour of the opening.

The subject chapter deals with the determination of rock mass types including characteristic rock mass parameters and the allocation of rock mass behaviour types for the Niagara Tunnel Facility.

Note: It is assumed that all geotechnical parameters with a range derived from [3.19] were determined according to chapter 1 clause 9 of [3.19]. Therefore no further modifications of the values were carried out by the Proponent. If no range was given the range was calculated according to chapter 1 clause 8 of [3.19].

All geotechnical and hydrological findings for the project are summarized on drawing PD-01-1002 “Diversion Tunnel, Geotechnical Longitudinal Section” in a condensed form.

3.3.2 References

3.3.3 Summary of Geologic Conditions

Twelve stratigraphic formations are identified in the project area, which consist of sequences of sedimentary rock of Ordovician to Devonian age. These are namely the Guelph, Lockport, De Cew, Rochester, Irondequoit, Reynales, Neahga, Grimsby, Power Glen, Whirlpool and Queenston formations. Some of these are only a few meters thick. Eleven of the mentioned formations are expected to be encountered along the tunnel. The uppermost Guelph
formation will not intersect with the proposed tunnel alignment. The lithological spectrum of the encountered formation covers limestone, dolostone, sandstone and shale.

The rock formations dip gently towards south at an average rate of 5m/km. Major faults are not reported from the project area. However minor faults exist, forming thin shears parallel to bedding, up to a maximum thickness of 100mm and consisting of fine and coarse crushed material. It is assumed that these structures are related to stress relief, common in the Niagara region. Regional joint measurements revealed the existence of 4 major joint sets. The prevailing strike direction are 5°, 85°, 135° and 45°, all dipping at a high angle or vertical.

In situ stress conditions in southern Ontario are characterised by high horizontal stress, exceeding vertical stresses in parts significantly. The stress field is reported to be relatively consistent trending in a north-eastern direction. However the magnitudes of stress and the direction of the maximum stress can vary significantly depending on lithology, depth and topographical features.

Three major groundwater flow regimes are encountered in the rock formations of the project area. The uppermost occurs in the Guelph, Lockport and De Cew formations. These strata form the uppermost aquifer of the project area and are connected to surface water. This aquifer shows the highest permeability of the entire sequence. A second flow regime is associated with the low permeability strata of the Rochester, Neahga, Power Glen and Queenston formations, forming a system of aquitards. A third flow regime is associated with the deeper, higher permeable strata of the Irondequoit, Reynales, Thorold, Grimsby, Whirlpool and upper Queenston formations. These strata form deep lying aquifers. Groundwater elevations are reported to vary significantly from stratum to stratum and from location to location. Some groundwater heads encountered showed artésic behaviour with pressure heads above ground level. It is assumed that these characteristics are associated with the occurrence of natural gas. Water of the two lower flow regimes is reported to be highly corrosive and concrete aggressive, containing relevant amounts of chloride and sulphate. Chemical properties of the uppermost flow regime vary significantly depending on the influence of surface water.

Natural gas occurrence is common on the Niagara Peninsula. However the amounts of gas encountered during previous tunnel constructions were limited.

Geological/geotechnical input data have been derived from OPG documents [3.10]. Based on this data the Rock Mass Types and Rock Mass Behaviour Types have been defined.

Figure 3.1: Flowchart for the Geotechnical Design
3.3.4 Rock Mass Types

The rock mass types (RT) are defined using relevant geotechnical rock volumes including lithology, discontinuities and tectonic structures. The characteristics of the rock mass types are governed by:

- Lithology
- Properties of discontinuities
- Strength parameters of intact rock
- Conditions affecting parameters of intact rock and of rock mass

Six characteristic geotechnical parameters are used to define thirteen rock mass types for the Niagara Facility Tunnel project which are summarized in the following table 3.1.

3.3.5 Geotechnical Parameters

The geotechnical rock mass parameters are derived based on Hoek-Brown’s mass law described in detail in [3.6]. The general form of the Hoek-Brown’s failure criterion is:

\[ \sigma_1 = \sigma_3 + \sigma_{ci} \cdot \left( m_b \cdot \frac{\sigma_3}{\sigma_{ci}} + s \right)^a \]

\( \sigma_1, \sigma_3 \) are the major and minor principal effective stresses
\( m_b \) is the Hoek-Brown constant for rock masses
\( s, a \) are parameters describing rock mass properties
\( \sigma_{ci} \) is the uniaxial compressive strength of the intact rock (obtained from [3.19], table 6.3)

The Hoek-Brown criterion thus establishes a connection between the principal effective stresses. The rock mass parameters \( m_b, a \) and \( s \) can be derived by means of the following parameters:

- Hoek-Brown constant for intact rock \( m_i \)
- Geological Strength Index \( GSI \)

Values for Hoek-Brown constant \( m_i \) were derived using the \( m_i \)-chart provided with the software RocLab [3.12]. The \( GSI \) is a parameter introduced by Hoek in 1994, providing a numerical rating of the rock masses based on the structure and discontinuity surfaces of the rock mass. The \( GSI \) values were derived by evaluating average joint spacing and surface conditions of the individual rock formations, using the \( GSI \)-chart provided in [3.1] (see also Appendix 3.2).

</table>

* av. spacing
** min-max (av.)
The relevant information concerning average joint spacing and discontinuity surface conditions were derived from [3.10] and [3.19]. These values enable the parameters \( s \) and \( a \), to be defined as follows:

\[
m_b = m_i \cdot \exp\left( \frac{GSI - 100}{28 - 14D} \right)
\]

\[
s = \exp\left( \frac{GSI - 100}{9 - 3D} \right)
\]

\[
a = \frac{1}{2} + \frac{1}{6} \left( e^{-GSI/15} - e^{-20/3} \right)
\]

\( D \) (Disturbance Factor) is a factor which depends upon the degree of disturbance to which the rock mass has been subjected by blast damage and stress relaxation. It varies from 0 for undisturbed in situ rock masses to 1 for very disturbed rock masses. Due to the planned excavation method the \( D \)-Factor was generally assumed to be 0.

The Hoek-Brown criterion serves to derive the Mohr-Coulomb parameters \( \phi' \) and \( c' \). Furthermore, the modulus of elasticity using the parameters \( \sigma'_{ci} \) and \( GSI \) can also be determined.

\[
\phi' = \sin^{-1} \left[ \frac{6am_b(s + m_b \sigma'_{3n})^{a-1}}{2(1 + a)(2 + a) + 6am_b(s + m_b \sigma'_{3n})^{a-1}} \right]
\]

\[
c' = \frac{\sigma'_{ci}(1 + 2a)s + (1 - a)m_b \sigma'_{3n} \left[ (s + m_b \sigma'_{3n})^{a-1} \right]}{(1 + a)(2 + a)\sqrt{1 + (6am_b(s + m_b \sigma'_{3n})^{a-1})/((1 + a)(2 + a))}}
\]

where \( \sigma'_{3n} = \sigma'_{3\text{max}}/\sigma_{ci} \).

The value of \( \sigma'_{3\text{max}} \) is the upper limit of confining stress over which the relationship between the Hoek-Brown and the Mohr-Coulomb criteria is considered.

\[
Em(\text{GPa}) = \left( 1 - \frac{D}{2} \right) \sqrt{\frac{\sigma_{ci}}{100}} 10^{(GSI-10)/40} \quad \text{for} \ \sigma_{ci} \leq 100
\]

\[
Em(\text{GPa}) = \left( 1 - \frac{D}{2} \right) 10^{(GSI-10)/40} \quad \text{for} \ \sigma_{ci} > 100
\]

The results of the calculations are listed in table 3.2.

1) It is assumed that the values for UCS of intact rock, obtained from GBR A, table 6.3, were determined according to chapter 1, point 8 and 9 of GBR A
3.4 Rock Mass

Rock mass behaviour is decisive for the design of the required initial support and final lining of a tunnel. Various methods have been applied in order to determine rock mass behaviour along the proposed tunnel alignment including block stability analyses and FE-modelling. Details of the applied methodology are summarized in [3.17].

3.4.1 Boundary Conditions

The boundary conditions influencing the rock mass behaviour can be listed as follows:

- Rock mass properties
- In situ stress conditions
- Groundwater conditions
- Orientation of the opening
- Dimension and shape of the opening

3.4.1.1 Rock Mass Properties

Rock mass properties to be encountered along the tunnel are presented in chapters 3.3.4 and 3.3.5.

3.4.1.2 In Situ Stress Conditions

Extensive in situ testing was carried out in order to determine stress conditions along the tunnel alignment. The results to be considered for the tunnel design are presented in table 6.14 of the [3.19]. These results cover the Concept Alignment which is basically situated within the Queenston Formation.

For the Proposal, in situ horizontal stress conditions included in GBR-A were adopted for design. Vertical stress is assumed to be governed by the overburden only with the exception of the outlet section. There 3D in situ stress measurements indicate, that vertical stresses are 30% higher than stresses induced by overburden only.

The following table 3.3 summarizes the in situ stress conditions considered for the design.

Table 3.3: Stress Regimes for Design Purposes

Several attempts have been made in the past in order to predict the effect of in situ stress on rock mass behaviour and support requirements for underground structures. Hoek and
Brown introduced the Hoek-Brown stability classification based on their experiences from deep-lying mines in South Africa. This classification system is based on the evaluation of the relation between $\sigma_t$ and $\sigma_c$ for a $K_o = 0.5$. To overcome this limitation the Damage Index was introduced, which can be correlated to the Hoek-Brown stability classification (see Figure 3.2).

$$Di = \frac{\sigma_{max}}{\sigma_c}$$

where:

$\sigma_{max} = 3\sigma_1 - \sigma_3$ is the maximum tangential boundary stress, and

$\sigma_c$ is the uniaxial compressive strength of the intact rock.

The below figure shows the correlation between $Di$ and the Hoek-Brown stability classification. According to this classification:

- $\frac{\sigma_1}{\sigma_c} \leq 0.1$: stable rock mass, no support required
- $\frac{\sigma_1}{\sigma_c} = 0.2$: minor spalling, light support
- $\frac{\sigma_1}{\sigma_c} = 0.3$: severe spalling, moderate support
- $\frac{\sigma_1}{\sigma_c} = 0.4$: heavy support required
- $\frac{\sigma_1}{\sigma_c} \geq 0.5$: extremely difficult to support
The depth of stress induced failure was estimated using the below formula.

\[
\frac{Rf}{a} = 0.49(\pm0.1) + 1.25 \ast Di
\]

\( Rf \) is the depth of failure measured from the tunnel center
\( a \) is the tunnel radius.

Both procedures are derived from [3.8]. The results of the calculations are summarised in Appendix 3.3 for the four tunnel sections shown in Table 3.3. They were used for choosing the necessary model for evaluating rock mass behaviour (see Chapter 3.4.2).

### 3.4.1.3 Groundwater Conditions

Groundwater can have a major impact on rock mass behaviour during tunnel construction. Groundwater conditions along the proposed tunnel alignment are expected to vary significantly due to the encountered rock mass properties. Significant groundwater inflow is to be expected within the Lockport and the De Cew Formations. It is assumed that groundwater has no influence on rock mass behaviour of those formations, due to their rock mass properties.

Groundwater inflow in the below situated formations is very limited. Thus it is assumed that groundwater has, despite rock mass swelling, no influence on rock mass behaviour.

Within shale formations, groundwater can trigger rock mass swelling if appropriate clay minerals are available.
Groundwater inflow to the tunnel was estimated following the procedure described in [3.11]. This procedure follows Heuer’s experience [3.3], which shows that tunnel inflow is 1/8 of that predicted by Goodman’s equation [3.2].

\[
Q = \frac{2 \pi kf H}{\ln\left(\frac{2H}{r}\right)} \cdot \frac{1}{8}
\]

where:

- \(Q\) is tunnel inflow in m³ per second
- \(kf\) is the permeability
- \(H\) is the groundwater table above tunnel center
- \(r\) is the tunnel radius (the calculations were carried out for a tunnel radius of app. 7,2m).

The following table 3.4 summarizes the results of these calculations.

</tbody>
</table>

Note that the above shown sections are listed in direction of the tunnel advance.

The results of the calculations were compared to the water inflow encountered in the test adit which was in total 0,74l/s during and 0,14l/s after tunnel construction for the 612m long tunnel. The test adit is situated in the Queenston Formation, therefore only calculation results for the Queenston Formation can be directly correlated to these findings.

In addition the hydrochemical properties of the encountered groundwater were evaluated in order to predict the influence on steel and concrete. Testing results showed that the groundwater encountered in the formations below the Eramosa member of the Lockport formation contain in general significant contents of chloride and sulphate and thus is to be classified as highly corrosive and concrete aggressive. Excluded from this general assumption has to be a tunnel section around borehole NF4 where chloride and sulphate contents are
significantly lower. It is assumed that surface water inflow from the existing channel is causing dilution of the groundwater.

The Lockport formation shows highly variable chloride and sulphate contents due to the changing influence of surface water all along the tunnel alignment.

The results of the evaluation of the hydrochemical testing with respect to the tunnel alignment are summarized in Appendix 3.1. The assumed distribution of the hydrochemical properties along the tunnel alignment is shown in [3.14].

3.4.1.4 Orientation of Opening

The orientation of the opening relative to the major discontinuity sets governs the stress relevant for the tunnel design. It also has a major impact on size, shape and stability of rock wedges formed by the intersection of discontinuities and the tunnel opening. Therefore the orientation of the opening is considered in the block stability analysis as well as the FE-analysis.

3.4.1.5 Dimension and Shape of Opening

The distribution of stress around the tunnel opening is governed to a large extent by the size and shape of the opening. They also affect size and shape of potentially unstable blocks during tunnel excavation. Therefore the size and shape of the opening are considered in the block stability analysis as well as in the FE-analysis.

The bored part of the Diversion Tunnel has a circular excavation cross section of 14.44 m diameter. The circular cross section is favourable for redistribution of stresses, which develop in the rock mass around the excavation opening. Rock mass loosening will such be minimized.

A short section of tunnel, adjacent to the Intake and Outlet structures, is excavated by mining methods. The tunnel cross section has to be changed from circular to square on a length, which corresponds to approximately one tunnel diameter. The square end of excavation is up to 19 m wide. The excavation cross section at the interface to the bored tunnel is horse-shaped and 16 m wide and 17 m high at its top.

The cross sections for channels at the Intake and the Outlet area is generally rectangular.

3.4.2 Rock Mass Behaviour Types

In total 8 basic rock mass behaviour types have been identified along the tunnel alignment. It has to be mentioned that some rock mass behaviour types can coexist along a tunnel section since some types represent short term rock mass behaviour (e.g. wedge failure) and some types represent long term rock mass behaviour (e.g. swelling or squeezing rock). During future design phases it may be found reasonable to refine this rock mass classification by partitioning the identified rock mass behaviour types into more subtypes.
Note that rock mass behaviour types are defined considering an endless long tunnel without any construction stages and support measures.

3.4.2.1 Behaviour Type 1: Stable Rock

Rock mass behaviour was analysed using block theory. The block modelling was carried out applying the software UNWEDGE [3.13].

**In Situ Stress Conditions**: in situ stresses significantly exceed rock mass strength

**Groundwater Conditions**: groundwater conditions are varying from damp to wet

**Rock Mass Behaviour**: shale formations with a considerable content of swelling clay minerals are prone to rock mass swelling resulting primarily in invert heave; stress relief and the presence of fresh water are substantial for the swelling process; shale interbeds in the sandstone and carbonate formations may also be subject to swelling, however the presence of sandstone and carbonate interbeds tend to inhibit the overall deformation; the swelling process predominatingly occurs in the invert due to gravity related water accumulation, however it can occur at any place around the opening where groundwater is present; long term rock squeeze and swelling are interrelated processes which can be difficult to distinguish

**Deformations**: long lasting deformations >20mm

---

**Sketch of assumed rock mass failure**: invert heave not in scale
3.5 Excavation and Support

3.5.1 Requirements

The requirements for excavation and support are based on the following conditions:

- Safety for working personnel
- Structural stability of excavation and support
- Safety against wedge and block failure
- Stability of the excavation face
- Avoidance of rock mass loosening
- Initial lining capacity
- Allowable deformations

The Diversion Tunnel is aligned through built-up area. However ground conditions are considered to be favourable for tunnelling, that only with a very shallow rock cover surface effects will be registered.

3.5.2 Excavation Methods

The bored tunnel is excavated by means of a hard rock Tunnel Boring Machine (TBM). The TBM consists of main body, cutter head and grippers. Disks on the rotating cutter head break the rock mass, which is conveyed in form of loose chips to the back of the TBM. The forces which develop as a result of forward movement of the TBM are transferred back to the ground by grippers. The TBM as such is only approx. 20 m long, however a 100 to 200 m long backup system is required to manage all the logistics for tunnel excavation and support installation.

The short sections of tunnel at the Intake and Outlet, which require a cross section, which deviates from circular are excavated by drill and blast. Smooth-blasting methods have to be employed to avoid undesired vibrations and subsequent rock mass loosening. A horizontal drilling pattern is to be employed with a borehole length not longer than 4 m.

3.5.3 Support Measures

The following support measures are used and represent in total the initial lining:

- rock dowels
- steel wire mesh
- steel ribs
- shotcrete

A dimple membrane is placed on to the intrados of the initial lining, where water seepage has to be channelled into the temporary construction drainage system to facilitate tunnel construction.
3.5.3.1 Rock dowels

Fast acting standard Swellex or equivalent rock dowels with a length \( L = 2.4 \) m and \( L = 3.6 \) m are used to be installed just behind the cutterhead of the TBM.

For the installation of rock dowels further back from excavation, cement/resin grouted rock dowels with a length of \( L = 2.5 \) m to \( 4.0 \) m are used.

The rock dowels are installed through the steel ribs (UPN-profiles) or with an anchor plate (\( L \times W \times T = 100 \times 100 \times 8 \) mm) at its base.

They serve as rock reinforcement through bedding – and shear planes and improve block stability. The steel wire mesh installed in the tunnel crown for protection is also attached with rock dowels and short anchors.

3.5.3.2 Steel Wire Mesh

Steel wire mesh with bar size of 6 mm and bar-spacing of 100 mm by 100 mm is installed to
- reinforce the shotcrete and
- to protect personnel from falling rock particles until shotcrete is installed.

In addition the welded steel wire mesh facilitates the application of shotcrete to the tunnel crown and to the sidewalls in the bored tunnel.

3.5.3.3 Steel Ribs

Two types of steel ribs are used for the construction of the bored tunnel.

The light UNP-Profile is used as a crown support element in geological conditions, which require roof protection mainly. It is applied in form of
- UNP 100: \( H \times W = 50 \times 100 \) mm (10.6 kg/m)
- UNP 140: \( H \times W = 60 \times 140 \) mm (16.0 kg/m)

Where heavy steel support is required full round, steel sets are to be used in form of
- IPB 160: \( H \times W = 160 \times 160 \) mm (42.6 kg/m)
- IPB 260: \( H \times W = 260 \times 260 \) mm (93.0 kg/m)

Steel ribs are installed just behind the TBM cutter head with mechanical erectors.

3.5.3.4 Shotcrete

Shotcrete is considered the main supporting element of the initial lining.

The thickness of shotcrete lining depends on the type of rock support to be applied and is ranging from 50 mm to 300 mm. A shotcrete thickness larger than 200 mm is installed in 2 layers at least. Shotcrete thinner than 70 mm is not considered as a structural element. However it serves as a sealing layer to protect the ground from drying out or abrasive water.
3.5.4 Tunnel Support Application

The arrangement of mechanical and electrical parts on a TBM allows for two locations, where support of excavation may be regularly installed.

The location L1 is situated just behind the cutter head between 4 m and 7 m back from the excavation face. Steel ribs may be installed full round or as a light profile on the crown of the tunnel cross section. Steel wire mesh and rock dowels can also be installed at distinctive locations above springline, where support is not harmed by the gripper loads exerted to the side walls of the tunnel. Shotcrete application is possible in L1 but limited to the absolute minimum requirement. Sensible electronic and mechanical parts of the TBM, which are situated in L1 may be affected by dust and rebound material. Protection measures and cleaning of the TBM as a result of shotcrete application in L1 reduces the rate of tunnel advance considerably.

All support installation in L1 adversely affects the rate of tunnel advance, therefore the intention is to install the majority of the required ground support, from a working platform at location L2 situated 20 m to 40 m back from the excavation face.

Depending on the ground conditions, which prevail in the tunnel at certain locations it is important to gradually increase the amount of support in a way, that the reduction of tunnel advance rate is minimized, but the required level of safety for people working in the tunnel is always maintained.

It has to be acknowledged, that full support of the bored tunnel is only in operation some 40 m back from the excavation. However, the ground support required early is, depending on the prevailing ground conditions, installed already behind the cutter head of the TBM.

In order to allow for gradually increasing support installation in an organized manner, support types are defined.

3.5.5 Support Types

6 Types of support are differentiated for the bored Diversion Tunnel. The support types ranging from support, if required to heavy steel sets and reinforced shotcrete full round to cover a wide range in rock mass behaviour, which is anticipated for the project.

3.5.5.1 Support Type 1:

Support Type 1 consisting of a sealing layer of 50 mm thick shotcrete, which is reinforcement by steel wire mesh. The support type is to be applied in stable rock conditions with a uniaxial compressive strength comparable to lean concrete. Only if rocks are sensitive to water or will degrade if exposed to air the shotcrete and mesh is to be applied.
3.5.5.2 Support Type 2

In case blocks of ground are differentiable in otherwise stable rock conditions, Support Type 2 is to be applied. It consists of steel ribs in form of UNP-100 profiles, which are bolted with a limited number of rock dowels to fix steel wire mesh to the tunnel crown and sides.

This arrangement shall provide safety for personnel working at the front of the TBM. Further back the steel support is covered with a layer of shotcrete (70 mm thickness) in the top section of the tunnel and additional rock dowels are installed. In case of seepage water dimple membrane panels are fixed to the tunnel crown and wall to drain the water into the invert area. If necessary in ground sensitive to water sealing shotcrete is applied to the invert section of the tunnel equal to Support Type 1.

3.5.5.3 Support Type 3

Support Type 3 is used in friable ground, where small blocks of ground tend to fall from the tunnel crown if left unsupported. It consists of steel rips UNP 140, rock dowels 3,6 m – 4,0 m long and steel wire mesh, which is installed close to the front of the TBM. Further back (i.e. working platform) reinforced shotcrete (t = 100 mm) and more rock dowels are installed to support the full circumference of the tunnel.

3.5.5.4 Support Type 4

Close to the intersection of the tunnel crown and major bedding planes, an increasing number and size of blocks of ground is to be expected. Support Type 4 consisting of steel profiles UNP 140 at close spacing, rock dowels 3,6 m to 4,0 m long and steel wire mesh is to be applied close to the front of the TBM. Reinforced shotcrete (t = 150 mm) and additional rock dowels are installed from the working platform of the TBM that support around the full circumference of the tunnel is realised.

3.5.5.5 Support Type 5

In squeezing ground, where slabbing and spalling is experienced soon after excavation Support Type 5 is to be installed. Support Type 5 consists of steel ribs in form of mid weight IPB 160 steel sets, which are installed close to the front of the TBM around the full circumference of the cross section. As for support types 2 to 4, steel wire mesh is installed in the tunnel crown to provide safety of the personal working at the TBM front. 200 mm of reinforced shotcrete applied from the working platform of the TBM full round is completing Support Type 5.

3.5.5.6 Support Type 6

Support Type 6 is to be installed in heavily squeezing rock, where spalling and slabbing is experienced even in front of the excavation face. Heavy IPB 260 steel sets and reinforced shotcrete (t = 100 mm) are to be installed at the front of the TBM. Additional shotcrete (t = 200 mm) and mesh reinforcement is installed at the working platform to support the full circumference of the excavation cross section.
3.5.6 Geotechnical Sections along the Tunnel Alignment

3.5.6.1 General

In order to allocate the support types, rock mass behaviour along the tunnel alignment has been evaluated. Five tunnel sections have been identified, which suggest consistent rock mass behaviour being encountered. The following chapters summarize the geological, geotechnical and hydrogeological conditions for each of these sections and the prevailing rock mass behaviour. More detailed information of the geological and geotechnical properties of the encountered rock mass types is provided in chapters 3.3.4 and 3.3.5. The description of the tunnel sections starts at the outlet structure and proceeds to the intake structure.

The following issues apply more or less to all defined tunnel sections:

- The length of each section is based on the tunnel axis. Prolonged interfaces in tunnel crown or invert are not considered when estimating the section length. The length of tunnel sections was rounded to 5m.

- Significant overbreak has to be expected in all tunnel sections where weak bedding planes or flat lying shears occur above the crown. This may result in crown instability. During upslope tunnel advance overbreak is possible when approaching such a feature, during downslope tunnel advance overbreak may occur when leaving such a feature. The depth of the overbreak is controlled by the distance to the overlying plane. During previous tunnel construction works, crown slabs of up to 0,5m were recorded. Relevant discontinuities are reported from all formations encountered in the project area.

- Where rock mass spalling and slabbing occurs, it is expected soon after excavation took place.

- Shale units are prone to change in moisture content, which will result in the development of cracks and degradation of rock mass when surfaces are left unprotected. Due to previous construction experiences it is assumed, that it will take months before relevant cracks develop. Application of sealing shotcrete stops the process.

- Long term rock mass behaviour in terms of rock swelling has to be expected for all shale formations. Laboratory testing proved that even shale interbeds within the sandstone and carbonate units show swelling potential. However it is assumed that the nonswelling sandstone/carbonate interbeds inhibit overall deformation. Extent and range of the actual swelling will depend to a large extent on the presence of groundwater and the prevailing in situ stress conditions.

- Long term rock mass behaviour in terms of rock squeezing has to be expected within all sections. Previous construction experience reveals that even competent rock mass types like the Lockport formation show long lasting squeezing behaviour.
The prevailing Support Types applicable to each section of tunnel for the Proposal are shown on drawing PD-01-1002 “Diversion Tunnel, Geotechnical Longitudinal Section”. To cover a range of support, which may be used in a particular tunnel section, a distribution of applicable Support Types is defined by:

- Very applicable = 60% probability
- Applicable = 30% probability
- Less applicable = 10% probability

Based on this assumptions, the support measures (i.e. rock dowels, wire mesh, steel ribs and shotcrete) for the Diversion Tunnel are estimated.

3.5.6.2 Tunnel Section 1

Section Length: Starting at the outlet structure, the tunnel section has a length of app. 740m.

Geology/Geotechnics: The tunnel is descending from the outlet structure at a gradient of 7.62% towards the low point. Within this section the tunnel will intersect the total sequence of all formations relevant for the Niagara Tunnel Facility Project including Lockport, De Cew Rochester, Irondequoit, Reynales, Neahga, Thorold, Grimsby, Power Glen, Whirlpool and Queenston Q10 and Q9 formation. Thus the tunnel section is also characterised by frequent changes of lithology and rock mass properties. The spectrum of lithologies to be encountered includes limestone, dolostone, shale and sandstone. The rock mass is in general slightly to moderately fractured and fresh to slightly weathered. In situ stress conditions are expected to be homogeneous throughout the section but their effect on rock mass is changing due to the variability of rock mass properties. In some parts the in situ stresses are expected to exceed rock mass strength in some parts they don’t.

Groundwater Conditions: Groundwater conditions are expected to vary between dry and wet. The later can be expected to prevail in Irondequoit, Reynales, Thorold, Grimsby, Whirlpool and Queenston Q10 and Q9 formations. In the tunnel section intersecting the Lockport and De Cew formation no significant groundwater inflow is expected due to grouting in the outlet section.

Expected Rock Mass Behaviour: Rock mass behaviour is expected to be stable to friable and varying within short distance due to frequent changes of rock mass and rock mass properties. In case failure occurs in the rock mass, the prevailing failure mode will change between failure induced by stress and/or along discontinuities, resulting in rock mass slabbing and spalling and/or wedge failure.

3.5.6.3 Tunnel Section 2

Section Length: app. 765m

Geology/Geotechnics: This tunnel section is situated entirely within the Queenston formation, members Q10 to Q6. The prevailing lithology is shale. The rock mass is slightly to moderately fractured and fresh to slightly weathered. In general in situ stress conditions...
exceed rock mass strength throughout the tunnel section. The low point of the tunnel is falling within this section. Thus there is both descending and ascending tunnel advance.

**Groundwater Conditions:** Groundwater conditions are expected to vary between dry and wet. The later can be expected to prevail in formation member Q10 and Q9 due to the higher degree of fracturing.

**Expected Rock Mass Behaviour:** Rock mass behaviour is expected to be friable to squeezing. More frequent than in Section 1, failure induced by stress and along discontinuities is expected. This is the prevailing short term failure mode in the rock mass, resulting in wedge failure and rock mass slabbing and spalling.

### 3.5.6.4 Tunnel Section 3

**Section Length:** app. 530m

**Geology/Geotechnics:** This tunnel section is situated entirely within the Queenston formation, member Q7 and Q6. The prevailing lithology is shale. Within Q6 a gypsum nodule horizon occurs. The rock mass is intensely fractured and slightly weathered. In situ stress conditions exceed rock mass strength throughout the tunnel section, in some parts significantly. The tunnel is passing under the buried St. David’s Gorge with shallow rock cover. Tunnel advance is ascending at a gradient of 0,10% for the proposed alignment.

**Groundwater Conditions:** Groundwater conditions are expected to vary between dry and wet. Wet conditions are expected to prevail due to intense fracturing.

**Expected Rock Mass Behaviour:** Rock mass behaviour is expected to be squeezing with sections of tunnel classified friable. Failure induced by stress is expected to be the prevailing short term failure mode in the rock mass, resulting in rock mass spalling and slabbing. Block failure may also occur due to intense fracturing.

### 3.5.6.5 Tunnel Section 4

**Section Length:** app. 7280m

**Geology/Geotechnics:** This tunnel section is situated entirely within the Queenston formation, member Q10 to Q6. The prevailing lithology is shale. Within formation member Q6 a gypsum nodule horizon occurs. The rock mass is slightly to moderately fractured and fresh to slightly weathered. In general in situ stress conditions exceed rock mass strength throughout the tunnel section. The geological conditions are comparable to Section 2. Tunnel advance is ascending at a gradient of 0,10%.

**Groundwater Conditions:** Groundwater conditions are expected to vary between dry and wet. The later can be expected to prevail in formation member Q10 and Q9 due to their higher degree of fracturing.

**Expected Rock Mass Behaviour:** Rock mass behaviour is expected to be friable to squeezing. Failure induced by stress and along discontinuities is expected to be the prevailing short
term failure mode in the rock mass, resulting in wedge failure and rock mass slabbing and spalling.

3.5.6.6 Tunnel Section 5

**Section Length:** app. 1090m

**Geology/Geotechnics:** Within this section the tunnel will intersect the total sequence of all formations relevant for the Niagara Tunnel Facility Project including Lockport, De Cew Rochester, Irondequoit, Reynales, Neahga, Thorold, Grimsby, Power Glen, Whirlpool and Queenston Q10 and Q9 formations. Thus the tunnel section is also characterised by frequent changes in lithology and rock mass properties. The spectrum of lithologies to be encountered includes limestone, dolostone, shale and sandstone. The rock mass is in general slightly to moderately fractured and fresh to slightly weathered. In situ stress conditions are expected to be homogeneous throughout the section but their effect on rock mass is changing due to the high variability of rock mass properties. In some parts the in situ stresses are expected to exceed rock mass strength in some parts they don’t. In general the geological conditions are comparable to section 1. Tunnel advance is ascending at a gradient of 7.23%.

**Groundwater Conditions:** Groundwater conditions are expected to vary between dry and wet. The later can be expected to prevail in Irondequoit, Reynales, Thorold, Grimsby, Whirlpool and Queenston Q10 and Q9 formations. Tunnel sections intersecting the Lockport and De Cew formations can expect groundwater conditions which vary between wet and flowing. Significant groundwater inflow can occur within this part of the section.

**Expected Rock Mass Behaviour:** Rock mass behaviour is expected to be stable to friable. Due to lithological changes of the rock mass a frequent variation of rock mass properties is expected. The prevailing failure mode will change between failure induced by stress and failure along discontinuities, resulting in rock mass slabbing and spalling and/or wedge failure.

### 3.6 Invert Segments

Invert segments made of precast concrete are placed to support rails of the construction trains for material supply and the backup system of the TBM. Any seepage water entering the tunnel during excavation shall also be diverted to the deep point of the alignment via the invert segments.

The concrete may be reinforced with standard bar reinforcement or steel fibres. There is no connection planned between invert segments and the initial lining, which is installed for rock support during excavation of the tunnel. However invert segments are connected to the final lining and participate in carrying all permanent design loads. Two types of standard segments are envisaged for use Type A is 600 mm thick and installed in the upper levels of the tunnel alignment. Type B is 700 mm thick and installed in the deep sections. Purpose
Built segments are placed at locations where the lining thickness changes to avoid abrupt steps at interfaces. Up to 100 mm difference in lining thickness can be compensated without causing significant effects on the flow rate of water transfer.

3.7 Cavity Grouting

In the permeable section of the Lockport and Decew Formations cavity grouting is envisaged to seal the excavated Diversion Tunnel.

Cavity grout is injected through four metre long boreholes evenly distributed around the cross section of the tunnel and spacing app. 2.5 m in longitudinal direction. Since no long-term use is expected from cavity grouting, Ordinary Portland Cement is used for binder. If mortar or cement grout is to be applied, will be determined on site and confirmed by grouting trials. Also the suitable water-binder-ratio is to be determined on site.

To determine material quantities for bidding purpose a water-binder-ratio of 1:1 is selected. Based on the experience described in the GBR, section 8, 100 kg take of binder/cement is calculated per meter borehole length in the Diversion Tunnel. The length of section to be grouted is assumed to be 20% of the Diversion Tunnel located in the Lockport and Drew Formations. The interfaces between the Diversion Tunnel and major bedding planes will also be treated by cavity grouting, if required.

On average 25 m deep holes spacing 3 m are drilled for grouting purposes at the Intake Structure and Channel. A grout-take assumed to be 200 kg of cement/binder per meter borehole is considered in the assessment of quantities.

30 m deep holes spacing 3 m are drilled for grouting purposes around the periphery of the Outlet Structure and Canal. A grout-take of 100 kg of cement/binder per meter borehole is considered in the assessment of quantities.

The cavity grouting operation is carried out in several phases using new groutholes to be drilled at intermediate locations and checking the efficiency of the grouting operation after each phase is finished.

3.8 Waterproofing Membrane System

To prevent seepage of aggressive ground water into the Diversion Tunnel, a waterproofing membrane system is placed between the initial lining and the final lining. The waterproofing membrane system consists of

- regulating shotcrete
- Membrane-backed geotextile
- waterproofing membrane
Regulating shotcrete is to provide the smooth surface, which enables membrane installation and counteracts any potential damage on sharp corners and edges of the waterproofing membrane during placement, concreting and during the specified design life.

The geotextile also protects the waterproofing membrane and enables subject to the thin membrane-backing the flow of interface grout.

The waterproofing membrane is designed to act as an impermeable layer between initial and final lining and to sustain all pressures and strains throughout the specified design life of 90 years.

### 3.9 Final Lining

The final lining consists of cast in place concrete without steel reinforcement. The final lining is min. 600 – 700 mm thick and compressed by interface grouting at high pressures to sustain internal water pressures, which develop during standard operation, without cracking. It is erected with using approx. 12 m long steel shutters, that run on the invert segments installed before hand. The steel skin used for formwork is designed to fullfill tight smoothness criteria set for flow of water in the Diversion Tunnel. Abrasivity is also counteracted by the smoothness of the concrete surface such maintained. Ordinary Portland Cement is used for the manufacture of final lining concrete, since particular resistance to aggressive water is not required due to the presence of the waterproofing membrane. When interface grouting is executed at pressures higher than the external water pressure, the presence of groundwater around the outside of the tunnel can be excluded.

### 3.10 Contact Grouting

Contact grouting is to be carried out after concreting of the final lining is finished.

Contact grout is injected in the tunnel roof between the back of the final lining concrete and the waterproofing membrane. The aim is to close all voids, cracks joints and inconsistencies in the final lining concrete resulting from the concreting operation and to provide a tight interface between rock mass / initial lining and final lining. The contact grouting procedure is carried out through injection lines (hoses with values) installed in the roof of the tunnel.

The injection lines are spot-welded to the waterproofing membrane and have openings at regular intervals to release the grout. Cement grout consisting of Ordinary Portland Cement compatible to the final lining concrete is used.

For the determination of quantities a 10 mm gap is assumed around one quarter of the tunnel circumference in the roof area.
3.11 Interface Grouting

The interface grouting at pressure high enough to sustain internal water pressures has been originally developed for pressure tunnels and shafts at hydropower schemes. Grout is injected between initial lining and waterproofing system at pressures up to 30 bar to open the interface and prestress the final lining at one hand and the rock mass surrounding the tunnel on the other hand. The final lining is compressed and the rock mass around the tunnel is brought close to its original stress state before excavation of the tunnel took place.

The interface grouting operation is carried out after final lining installation in stages through a system consisting of grout-hose-rings installed at the surface of the initial lining.

Circular grout hose lines with valves at regular intervals are placed between initial lining and the waterproofing membrane system. This shall ensure an evenly distributed flow of grout along the membrane-backed extrados of the waterproofing system and facilitate filling of joints and cracks in the initial lining and rock mass with grout.

The ends of grout hoses are guided through the waterproofing membrane system and through the cast in place final lining into the tunnel. By pumping grout to the interface between membrane and initial lining a circumferential joint is opened and filled with cement grout. The final lining is prestressed against the rock by the grout pressure acting in the circumferential joint. The deformations of initial lining, final lining and the rock mass are locked after the cement grout has hardened.

Since grout escapes into the cracks and fissures of the rock mass, the ground is consolidated and sealed against ingress of water at the same time.

The interface grouting rings are located at regular intervals (3 m to 4 m). Grout blocking rings are installed every 12 m approx. to control the flow of grout.

The grouting procedure follows a defined pattern of pressure application with aid of two or more pumps, hence creating a consistent flow of grout along the tunnel. For estimating purposes 100 m advance rate per day is assumed for the interface grouting process. The average gap to be filled with cement is assumed to be 3 mm thick.

Grouting is carried out in a first phase at every other interface grouting ring from both ends of the grout hose. If necessary the remaining rings are grouted in a second phase of interface grouting. The success of grouting is carefully monitored by precise deformation measurements of the final lining around the full circumference of the tunnel. Pumping pressures defined by structural analysis, are such controlled within allowable limits.

All operational pressures and loads are carried by the compressed final lining concrete ring after successful grouting. Shrinkage of concrete and the shrinkage due to the drop in temperature when filling the tunnel with water are carefully considered in calculations for the required grouting pressure.
3.12 Dewatering System Shafts

5 dewatering shafts will be located on the centreline of the tunnel at approx. km 8.9 of the Diversion Tunnel so that the Owner’s pumping equipment can be positioned over the tunnel invert. Each shaft is circular and drilled with a minimum diameter of 1.05 m in overburden and 0.915 m in rock to accommodate a min. 750 mm steel pipe as shown on the Proposal Drawings. The pipe is coated with 3 HDPE and lined with fusion bonded epoxy to resist the corrosion-aggressive environment. The annulus around the pipe is grouted to prevent water seepage between different geological formations along the outside of the pipe. One 2.0 m x 2.0 m wide sump is provided at the invert below one of the dewatering shaft locations such that a submersible pump can be positioned below the tunnel invert to achieve the required operating submergence in the final stage of dewatering.

The water pumped from the tunnel during dewatering will be discharged into a Water Collection Sump and conveyed via a buried 227 m long 1.0 m dia. HDPE Pipe and a 3.45 m wide chute into the SAB2 Canal.

The shafts are capped for normal operation of the tunnel and the cap is protected from pressure surges with air vents.

3.13 Intake Structure, Outlet Structure and Channels

3.13.1 Intake Structure, Intake Channel

The location and dimensional geometry of the intake channel and intake approach wall are fixed as defined on the Concept Drawings. The adjustments for final tunnel slope and diameter are shown in the Proposal Drawings. The alignment and dimensional geometry of the ice accelerating wall is generally shown on the Concept Drawings. The design of surfaces of structures and excavations as shown on the Proposal Drawings is intended to convey water smoothly into the intake structure and shall provide satisfactory performance for both open water and ice conditions.

The intake structure location, internal dimensional geometry, and transition from the shape at the entrance to the circular shape of the tunnel are fixed as defined on the Concept Drawings. Adjustment to the geometry for tunnel diameter and tunnel slope is shown on the Proposal Drawings.

100-mm of compressible material is provided between the rock surface of excavated walls and the intake and outlet structures to accommodate movement due to time-dependent deformations of the rock.

Suitable venting will be provided at the intake behind the Sectional gate to permit aeration of the tunnel during filling and dewatering. Vent sizing is 1.0 m diameter, but will be adjusted such as to limit noise levels during filling and dewatering to the relevant noise restrictions in future design stages.
A cover will be provided over the top of the Sectional service gate openings in the intake structure to avoid the possibility of ice being drawn into the structure. The cover is of ample mass to prevent dislodgement and will be detailed at future design stages to prevent seizing of the cover after prolonged submergence. Appropriate lifting devices will be provided on the covers to enable the Sectional service gate follower to engage and lift the gate slot cover.

3.13.2 Excavations for Channels and Structures

Smooth plastering techniques will be employed to excavate the sides of the intake channel and outlet canal. Care is taken to ensure, that the rock beyond the excavation limits is not damaged or destabilized by the blasting operation. Any damaged rock will be removed and backfilled with concrete adequately tied back to sound rock to produce the required excavation lines.

The need for preset rock reinforcement prior to blasting for the intake excavation to secure the integrity of the foundation of the INCW control structure will be examined upon detailed inspection of the structure and surrounding ground conditions.

During excavation, methods will be employed to prevent damage to existing structures and buildings and affect operation of existing equipment. Blasting velocities will be carefully controlled and the affected structures will be monitored to ensure adequate control.

Any exposed shaly rocks (e.g. the Rochester Formation) or shale layers which are susceptible to deterioration upon exposure to wetting and drying cycles and large temperature differences will be immediately protected by sealing shotcrete.

Overburden slopes are designed subject to analysis results at 1:1.5 (temporary slopes for excavations of trenches, sumps, etc.) and 1:2 (permanent slopes) grades. Vertical excavations for trenches are only allowed to a depth of 1.2 m.

3.13.3 Outlet Canal Rock Plug Removal

The rock plug between the Outlet canal and the existing PGS canal will be removed by excavation under water. The outlet gate will be closed to provide balanced water conditions during rock plug removal.

The excavated material will be removed from the PGS canal and taken to the muck depot prior to the PGS canal being brought back into operation.

A sounding survey of the PGS canal will be performed before and after removal of the rock plug to verify that no excavated material remains within the PGS canal and the results submitted to the Owner.

Protection measures will be installed to ensure that no material is carried down the PGS canal during and after removal of the rock plug.
3.14 **Additional Ground Investigations proposed**

The rock surface in the area of the Diversion Tunnel crossing under the buried St’ David’s Gorge is steep and highly uneven that predictions of rock elevation are uncertain. Seismic investigations and several boreholes suggest, that the difference in rock surface elevation vary within meters by an order of magnitude (i.e. ± 10 m). Since the vertical alignment of the tunnel is aiming to be optimized during detail design stage in vicinity of the buried St’ David’s Gorge, several boreholes are proposed exactly on the tunnel axis to confirm the elevation of rock at the base of the gorge.

The geotechnical drilling operation will be concentrated between km 8+550 and km 8+850 of the Diversion Tunnel.

The borehole location are planned, where the seismic investigations predict the deepest elevations along the tunnel alignment.

3.15 **Instrumentation**

3.15.1 **Purpose**

Instrumentation will be installed and monitored until Final Completion by the Contractor.

Movements of existing structures and buildings affected by the Work are monitored to ensure their protection, structural integrity and safety.

In particular the existing Toronto Power Station and the Niagara GS Power Station will be closely monitored by precise levelling. Also the existing tunnels, as far as accessible, will be closely monitored. Where the Diversion Tunnel is bored at shallow depth with less than two diameter cover under existing roads, services and buildings, the surface will be monitored and any settlement and tilting documented.

It is proposed to monitor the response of rock adjacent to the tunnel at regular intervals of 200 m with convergence monitoring sections throughout the advance of tunnel excavation. In addition a long-term measuring section consisting of piezometers and extensometers is planned close to the dewatering shafts or tunnel piezometer holes, since the wiring for instruments could be integrated into the backfill of borehole casings. However it is intended, that such suitable monitoring section, where rock’s response to the tunnel during construction, filling and commissioning is maintained, is selected by the Owner.

3.15.2 **Instrument Types**

Surface movement monitoring (SM) is carried out with survey equipment and surface movement monitoring points (SMMP). The SMMP is a marker fixed to a surface, and used for the measurement of the vertical and horizontal movements of that surface. For SMMP permanent pins on structures or grouted rods in rock are used. Survey equipment
(theodolite, level, electronic distance measuring device, tape extensometer), is capable of measuring vertical and horizontal movements of the SMMPs to ±1 mm.

Borehole Extensometers (EX)— is a device installed in boreholes for monitoring the changing distance between two or more than two points along the axis of the borehole. The EX to be used is of the vibrating wire type and capable of determining the relative position of each anchor to the surface installation with a repeatability of ±0.1 mm. Multiple Point Borehole Extensometers or several Single Rod Extensometers will be used to measure differential movements at each location to be monitored.

Piezometer (PI)—A groundwater piezometer is a device that is sealed within the ground so that it responds only to groundwater pressures around itself. Tunnel Piezometers are used to measure the water pressure within the tunnel. Piezometers to be provided are of the vibrating wire type and shall be capable of measuring the head of water at the piezometer tip to a repeatability of ±0.1 m.

Plumbline—A plumbline is a device to measure the relative tilt of a structure between two or more locations and is used for predominantly vertical structural elements, such as walls of pits and shafts.

3.15.3 Surface Movement Monitoring

SM will be carried out on masonry, buildings and road structures like bridges from prior to commencing any excavation until completion of final structures or linings in the area affected by the excavation. Buildings include, but are not limited to, INCW structure Bays 1 to 53 and the INCW control and maintenance buildings, existing Toronto Power Station and the Niagara GS Power Station.

A series of SMMPs will be installed and monitored on the INCW structure on Bays 1 to 3 above the intake excavation with a spacing of no more than 5 m.

A series of SMMPs will be installed and monitored at the pier nose of Piers 1 and 2.

A plumbline will be installed at the pier nose of Piers 1 and 2 extending to rock level. The plumbline shall have measuring tables at min. three locations.

3.15.4 Excavation Monitoring

On 2 vertical or near vertical rock cuts at the intake and outlet excavations at approximately the midpoint horizontal extensometers will be installed, that have monitoring positions (anchors) at 20, 10, 5 and 2 m from the wall of the excavation. Electrical leads are in watertight conduits leading to a lockable watertight box located at the deck level, which allows long-term monitoring of wall movement.

3.15.5 Instrumented Tunnel Sections

The following instrumentation for long-term monitoring is provided for the section of the tunnel as selected by the Owner (see. Drawings PD-01-1008 and PD-01-1009: Diversion
Tunnel, Geotechnical Measurements and Diversion Tunnel, Geotechnical Measurements, Surface and Subsurface)

- A permanent array of eight extensometers that have monitoring positions (anchors) at 25, 10, 5, 2 and 1 m radially from the surface of the tunnel excavation. Installation is completed and the initial readings taken, subject to installation of the initial lining, before the tunnel face advances more than 25 m beyond the array. This array of extensometers is capable of being monitored remotely from the surface during the initial filling and operation of the tunnel.

- A permanent array of six piezometers around the exterior of one section of the tunnel final lining and one on the interior of the lining at the tunnel invert. The array of piezometers is capable of being remotely monitored from the surface during the initial filling and operation of the tunnel.

- Electrical leads for extensometers and piezometers are routed in watertight conduits, adequately fixed to the tunnel crown and extending up one of the boreholes used for dewatering shafts or tunnel piezometers leading to a lockable watertight box located at approx. ground level.

3.15.6 Tunnel Piezometers

(see. Drawing PD-01-1021: Diversion Tunnel, Tunnel Piezometers, Sections and Details)

Tunnel piezometric levels are measured at two locations along the alignment of the tunnel at approximate km 1.4 and km 7.3. Each location consists of two piezometers, 2 m to 20 m apart. The borehole for one piezometer is extending through the tunnel lining at the tunnel crown to the ground surface. The cable for the other piezometer is routed in watertight conduits embedded in the final lining to the same borehole. The final locations will be agreed with the Owner prior to installation.

Piezometer holes are cased with HDPE casings with a minimum 95 mm inside diameter. The annular gap between the rock and the casing will be grouted to prevent groundwater migration between the different rock formations.

Detailing of the piezometer fitting at the tunnel crown, shown on the Proposal Drawings, ensures that the velocity head is not measured and that degradation of the adjacent tunnel lining or fitting does not occur. The fitting is made of stainless steel and designed to facilitate maintenance or replacement of the instrument, in case damage does occur.

The piezometer pit at the ground surface, which contains the data logger is made of concrete and set out to a depth that problems of ground movement due to frost heave are prevented. A watertight, lockable cap is also provided.
4 STRUCTURAL DESIGN

4.1 Diversion Tunnel

The design basis and design criteria for the structural design of the diversion tunnel are included in the structural design analysis for the Diversion Tunnel, document PR-00-4001. Also any reference to standards and codes is given in this document.

4.2 Intake and Outlet Structures

The design basis and design criteria for the structural design of the intake and outlet structures are included in the Draft Design Basis for Concrete Structures. Further details are given in structural design analysis for Intake and Outlet Structures, document PR-00-4004. Also reference to standards and codes is given in these documents.

4.3 Intake and Outlet Canal

The design basis and design criteria for the slope design of the channels are included in the slope stability analysis for excavations, document PR-00-4003. Also reference to standards and codes is given in this document.

4.4 Dewatering Shafts, Pipes, Culverts and Minor Items

The design basis and design criteria for the design of dewatering shafts, pipes buried in the ground, culverts for transport of water and minor items like foundations and shallow shaft pits are included in the stability analysis documents PR-00-4002 and PR-00-4005. Also reference to standards and codes is given in these documents.

APPENDIX 3.2:  GSI-Chart

GSI System

Massive - very well interlocked undisturbed rock mass blocks formed by three or less discontinuity sets with very wide joint spacing
Joint spacing > 100 cm

Blocky - very well interlocked undisturbed rock mass consisting of cubical blocks formed by three orthogonal discontinuity sets
Joint spacing 30 - 100 cm

Very Blocky - interlocked, partially disturbed rock mass with multifaceted angular blocks formed by four or more discontinuity sets
Joint spacing 10 - 30 cm

Blocky/disturbed - folded and/or faulted with angular blocks formed by many intersecting discontinuity sets
Joint spacing 3 - 10 cm

Disintegrated - poorly interlocked, heavily broken rock mass with a mixture of angular and rounded rock pieces
Joint spacing < 3 cm

Foliated/laminated/sheared - thinly laminated or foliated, tectonically sheared weak rock; closely spaced schistosity prevails over any other discontinuity set, resulting in complete lack of blockiness
Joint spacing < 1 cm

\[ J_C = J_R / J_A \]

INTRODUCTION

1.1 General

This report provides a comprehensive stability analysis for the structural tunnel design for the proposed Diversion Tunnel. Induced stresses in the initial support due to excavation as well as short- and long-term stress analysis on the final lining are considered in detail. The type of analysis depends on the potential failure mode during excavation and installation of tunnel support. In order to determine the required tunnel support, the following calculation models are applied:

- 3 dimensional and 2 dimensional Finite Element Methods
- Elastic Beam–Spring–Model Methods
- Key–Block Theory Methods
- Convergence–Confinement Methods

The sequenced and combined application of these methods makes it possible to get a level of detail, which enables to evaluate a safe and economic tunnel design.

1.2 Diversion Tunnel Alignment

The proposal design follows the concept alignment in principle. Only below the buried St' David's Gorge, the alignment is slightly relocated to the north–west to gain maximum rock cover. In addition the alignment close to the existing outlet structure is moved away from underneath the existing Delivery Tunnel No. 1, to facilitate the drilling of the borehole for tunnel piezometers. The overall depth of the tunnel has been slightly reduced as compared to the Concept Design.

3 SUMMARY OF RESULTS

In the following an abridgement of the subsequent comprehensive documentation of all calculation results is presented:

3.1 Initial Support Design

a) Wedge Analysis:
   The wedge analysis is carried for support types 2 to 4, which are applicable for support of blocks which may fail. The results show that in general support types 2 to 4 are sufficient to support all rock loads produced by block failure. Restrictively it has to be mentioned that few blocks will require additional spot bolting.

b) "3 m slab":
   The calculations proof that a rock load due to a "3m slab" can be supported by one of the initial support elements:
   
   i. HEB 160 spacing 1.8 m, or
   ii. >20 cm shotcrete full round or
   iii. rock bolting, raster 0.9m x 2.0m, l=6m, F=240kN

c) Stress Induced Calculations:
   On the basis of preliminary calculations (using a Convergence-Confinement Method and 3D-FE Calculations) the relevant stress release factors and load-transfer factors (time-dependent load transfer to the individual support elements behind the face) have been derived for a subsequent use within detailed 2D-FE calculations. The results show that the individual support classes along the Diversion Tunnel are capable to support all short-term load effects.

3.2 Final Lining Design – Grouting Pressure – Internal Water Pressure

Based on the FE-method the interaction between primary lining and subsequently installed and pre-stressed final lining has been investigated. Hereby the initial support was simulated in such a way, that it does not contribute to any load-bearing capacity during operating time. In addition to rock loads the final lining is designed for:
a) Long-Term Grouting Pressure:
   The high pressure interface grouting has been designed to pre-stress the final lining and the surrounding rock such that internal water pressure does not mobilize any tensile stresses in the lining. Due to the internal water pressure (maximum 1.4 MPa) a long-term grouting pressure in the range of 0.15 to 0.77 MPa is to be expected.

b) Short-Term Grouting Pressure:
   The expected constrains of the final lining concrete due to shrinkage, creep and temperature has been analyzed in order to evaluate the short-term grouting pressure, which has to be applied to the individual sections. It results a relevant final lining shortening of maximum 0.5 % in radial direction. These constrains require a short-term grouting pressure in order of 1.45 to 2.15 MPa.

3.3 Short-Term Ground Behaviour

Generally in-situ stresses are characterized by high horizontal stresses, exceeding vertical stresses in parts significantly. Within this high-stress level environment stress changes and stress redistribution around excavation leads often to full mobilization of strength capacity of the rock. The failure zone that forms around the opening is then a function of the tunnel geometry, the excavation procedure, the in-situ stress regime and the strength of the rock mass.

Within the more competent rock formations of Lockport, DeCew, Irondeque, Reynales, Thorold, Power Glen and Whirlpool only small failure zones above the tunnel crown and below the invert can be observed. The calculations show that the weaker rock formations, such as Grimsby, Rochester and especially Neahga and Queenston tend to widespread areas of failure zones at the shoulders as well as underneath the invert. During interface grouting, the failure zones reach further into the rockmass at the shoulders as well as underneath the invert.

Within the rock mass the development of shear strains is small, thus softening behavior of the rock mass has not been observed. Sheared, weak bedding planes exist between many of the rock formations and within the Queenston Formation. Especially the primary bedding planes present between the subunits of the Queenston Formation will affect the stresses and strains around the tunnel during and after excavation. Using a discontinuum approach different bedding plane levels were considered: (a) 2 m above tunnel heading, (b) within tunnel – 3
m below heading, (c) in the centre of the tunnel opening. A sensitivity analysis indicated that the bedding plane above the tunnel crown is most severe for tunnel design. Calculation results in widespread failure zones below the invert and on top of the tunnel crown; shear displacement within bedding plane exceeds peak strength – therefore strain softening was introduced as soon as 10 mm shear displacement was reached in any point.

The failure zones do not affect the stability of the opening because the numerical calculations results in balanced forces.

3.4 Influence on Existing Structures

Along the proposed tunnel alignment the existing Diversion Tunnels 1 and 2 will be above the new excavation.

The FE-calculations show that the influences due to the excavation and lining installation, as well as operating with respect to stress and strain state are marginal. No significant increase of stresses around existing structures has been observed. Within the less competent rock strata marginal additional deformations will be mobilized, but mobilization of failure zones is restricted to a small area. This will be reviewed in detail design.

3.5 External Water Pressure

The high pressure interface grouting is designed to prestress the final concrete lining and the surrounding rock. Thus water seepage along the outside surface of the tunnel is prevented. However the water pressure from water seepage has been considered as a "worst case" scenarios.

3.6 Dewatering of the Tunnel

Dewatering of the proposed Diversion Tunnel has been considered as a temporary load case in the proposal design and will be considered as a normal load case in detail design.
3.7 Long-Term Analysis

a) Swelling:
   It is expected that swelling has not to be taken into account for the present tunnel lining system as the tunnel lining incorporates an impermeable water proofing membrane so that long-term rock swelling does not develop (no accessibility to fresh water). In addition the high pressure interface grouting, which is designed to pre-stress the final concrete lining and the surrounding rock, will additionally suppress potential swelling pressures.

b) Rock-Squeeze
   Squeeze is usually associated with the long-term creep behavior of rock, initiated by the relief of high in-situ horizontal stresses. The long-term behavior has been taken into account by using a reduced stiffness modulus $E_{\text{rock}}(t)$ for the time $t$. The potential stress increase around the excavated tunnel has been analyzed using the Convergence-Confinement Method. The long-term stress increase has then been applied to the FE-calculations. Those calculations proof that the final lining is able to support the long-term stress increase in the vicinity of the tunnel.
4 DESIGN CRITERIA

4.1 General

The purpose of the Design Criteria is to locate general criteria, technical background information, guidelines, requirements and procedures. This information will be used for the subsequent analysis and design of the initial support for excavation and of the final lining of the proposed Diversion Tunnel.

4.2 Lining System

Lining system design criteria assume tunnel construction will utilize a double shell lining consisting of an initial support and a final lining separated by a waterproofing membrane. The waterproofing membrane system prevents seepage between inside and outside of the Diversion Tunnel and acts as a suitable corrosion protection for the final lining. The final lining will be installed once tunnel excavation is completed. The initial support is designed to carry the rock loads, which develop during stress redistribution upon excavation.

High pressure interface grouting, which is designed to prestress the final concrete lining and the surrounding rock is applied, such that internal water pressure does not cause cracking of the final lining concrete and that water seepage along the outside surface of the tunnel is prevented.

4.3 Codes and Standards

4.4 Structural Materials

4.4.1 Shotcrete

In order to model time-depended behaviour of the shotcrete (creep and hardening), short term and longterm stiffness (modulus of elasticity) of the shotcrete are taken into account. For a short time after the tunnel lining installation, the so-called “young” shotcrete (i.e. the characteristics of shotcrete before it has reached final design strength) is used in calculations. A reduced modulus of elasticity (HME) is applied; This HME reflects the behaviour of ground, shotcrete material and reinforcement. The values for HME are derived from the literature [1].

</tr>
</tbody>
</table>

Table 1: Modulus of Elasticity for Young Shotcrete
For hardened shotcrete a value for Young's Modulus of 15,000 MPa is used.

4.4.2 Reinforcement

The reinforcement of the shotcrete has not been explicitly modelled in the calculations.

4.4.3 Rock Dowels

The load bearing capacity of a rock dowel in tension is determined by the ultimate tensile strength.

The shear strength of steel bars, according to the Mises's hypothesis, is given by:

$$\tau = \frac{\sigma_t}{3^{1/2}} = 0.58 \sigma_t$$

Where:  $\sigma_t$ = tensile strength,
$\tau$ = shear strength.

4.4.4 Steel Ribs

The following material properties apply in accordance with CSA S16-01 [a]:

Minimum yield stress $f_y$ = 410 MPa,
Modulus of elasticity $E_s$ = 200,000 MPa.

4.4.5 Final Lining Concrete

Normal density concrete has been applied to subsequent calculations and has at least the properties shown below (in accordance with CSA A23.3.94 [b]):

Specified compressive strength $f_c' = 35$ MPa at 28 days
Poisson's ratio $\nu = 0.2$
E-modulus $E_c = 4500\sqrt{f'_c}$
The actual compressive strength used in the calculation will be based on the 90 days strength as determined by testing.

4.5 Design Loads

4.5.1 Structural and Dead Loads

Dead load of structural and non-structural elements is based on unit weight and computed volume of the materials. The following unit weights is used:

- Unreinforced Concrete 24.0 kN/m³
- Structural Steel 78.5 kN/m³
- Rock / Soil see GBR for details [4]
- Water 10.0 kN/m³

4.5.2 Live Loads

Live Load consists of any non-permanent load placed on or in the tunnel.

4.5.3 Ground Pressure

Ground loads on the tunnel lining are not predetermined in FE-calculations, since full overburden is modelled.

Geostatic loads have to be defined in accordance with the load case considered for structural calculations with Beam Spring Models.

4.5.4 Hydrostatic Pressure

It has to be distinguished between the internal hydrostatic pressure and the external ground water pressure. Relevant water pressures to be applied to the subsequent calculations are summarized in chapter 5.2.6.

4.5.5 Seismic Loads

Underground structures are generally less sensitive to seismic effects than surface structures, therefore no seismic loads are considered for preliminary
design. At detail design stage a seismic analysis based on actual data will be carried out.

4.5.6 Thermal Forces

Temperature changes cause thermal strains and internal forces in the final lining. Temperature variations during and after concreting are related to heat of hydration. The temperature is assumed to cool down to approx. 10 °C on the shotcrete/rock interface (extrados) and to 10 to 20 °C (seasonal variations before filling the tunnel) on the intrados of the final lining concrete. When filling the tunnel with water, the concrete temperature is assumed to drop from max. 20 °C to a minimum of approx. 4 °C on the intrados. The extrados of the final lining remains at a temperature of 10 °C as a conservative assumption.

This drop in temperature will cause a design-relevant contraction of the lining. It results in a loss of prestress of the final lining as a consequence.

Table 2: Temperature Gradient in Final Lining Concrete

4.5.7 Concrete Shrinkage

Concrete shrinkage is caused by the migration of the excessive water from the interior of the concrete mass and leads to shortening of the concrete per unit length. Since the final lining is restraint the shortening of the concrete leads to stresses in the lining. Shrinkage strains are assumed to be constant over the entire lining thickness.
The shrinkage strain mainly depends on the ratio of volume to surface of the structure, on the drying time of the concrete and on the humidity of the environment.

A concrete shrinkage strain of $\varepsilon_s = -15.7 \times 10^{-5}$ is applied based on experience with comparable tunnel linings.

4.5.8 Concrete Creep

Creep will be taken into account by reducing Young’s Modulus for concrete. From experience a stiffness-reduction-factor between $\mu = 1.5$ and $\mu = 2.3$, dependent on the concrete age, may be assumed. In the calculations an average reduction factor of $\mu = 2.0$ is applied. This leads to a reduction of Young’s Modulus for concrete to 50%.

4.5.9 Long-term Rock Squeeze

4.5.9.1 General

The tunnel lining system for the Diversion tunnel is designed to be capable of adequately supporting all loads including those imparted on the lining from long-term rock swelling [2].

It is recognized, that high horizontal stresses are prevailing in the rock formations in Southern Ontario. Rock excavation at surface and underground relieves the initial state of stresses, providing an initiating mechanism for time-dependent deformation to occur.

4.5.9.2 Time Dependent Deformation Behaviour

It has to be emphasized that the time dependent deformation phenomenon is described in terms of “rock squeeze” and “swelling”. It is well recognized that these processes are interrelated, and the individual effects of each are difficult to distinguish. Both effects can continue for many years [4].

Squeeze is usually associated with the long-term creep behaviour of rock, initiated by the relief of high in situ horizontal stresses. There is a well documented history of rock ‘squeeze’ affecting surface excavations in the upper dolostones and dolomitic limestones. This squeeze, however, may include the effects of swelling of the shale interbeds in these rock units [4].
4.5.9.3 Swelling Behaviour

Swelling to be assumed for design purposes in the Queenston Formation is given in the Owner’s Mandatory Requirements [2]. There is no available data regarding suppression of swell potential for the other formations.

Generally swelling involves a volume increase and is initiated by the relief of the high in situ stresses. However, swelling also requires the presence of fresh water. The process is associated with ionic diffusion of salts from the connate pore water in the rock. The swelling phenomenon can be suppressed under applied stresses.

For swelling to occur, the necessary conditions are:

- the relief of initial stresses, which serves as an initiating mechanism,
- the accessibility to fresh water,
- an outward salt concentration gradient from the pore fluid of the rock to the ambient fluid.

The proposed tunnel lining system includes the following features:

- The tunnel lining incorporates an impermeable liner in form of a waterproofing membrane system. No accessibility for fresh water is allowed and long-term rock swelling does not develop.
- The state of effective stress in the rock mass after excavation affects the rate of swelling. The high pressure interface grouting, which is designed to prestress the final concrete lining and the surrounding rock will additionally suppress potential swelling pressures because effective stresses in the rock mass.

The processes “swelling” and “rock squeeze” are interrelated. Model assumptions for rock swelling are presented in chapter 5.2.4.3.

4.5.9.4 Rock Squeeze Behaviour

The rock expansion upon unloading observed in previous constructions [4] is not necessarily associated with the swelling of clay minerals, although in the presence of swelling clay minerals the time dependent deformation is generally greater.

Rock squeeze is defined as substantial time-dependent deformation in the vicinity of the tunnel as a result of load introduced by redistribution of stresses.
adjacent to the excavated tunnel. Model assumptions for rock squeeze behaviour are presented in chapter 5.2.4.4.

4.5.10 Load Combinations

For load combinations not including earthquake, factored loads are determined in accordance with CSA A 23.3. Herein the effect due to specified loads multiplied by a load factor $\alpha$, a load combination factor $\psi$ and an importance factor $\gamma$ is considered:

$$\alpha_D D + \gamma \psi (\alpha_L L + \alpha_T T)$$

where:

- Load factors $\alpha$ for:
  - Dead loads $D$: $\alpha_D = 1.25$
  - Live loads $L$: $\alpha_L = 1.5$
  - Temperature loads $T$: $\alpha_T = 1.25$

- Load combination factor $\psi$:
  - $\psi = 1.00$ when $L$ or $T$ is considered
  - $\psi = 0.7$ when a combination of $L$ and $T$ is considered.

- The importance factor is equal to 1.0 for all load combinations.

4.6 Analysis Assumption

4.6.1 Analysis Methods

The type of analysis depends on the potential failure mode during excavation and installation of tunnel support. The failure mechanism is generally differentiated into the following failure modes:

- failure of rock blocks,
- fracturing induced by stresses and/or discontinuities,
- progressive failure induced by stresses,
- failure induced ahead of tunnel face,
- failure of tunnel face.

The following calculation methods are used (also shown in the flowchart of Figure 1):
Figure 1: Flow Chart "Stress Analysis"
4.6.2 Initial Support

The initial lining is subject to variations in stresses and strains during its intended use. Rock load, water load, chemical/physical influence of aggressive water, swelling phenomena of the surrounding rock, swelling and shrinking processes in the concrete, etc. The resulting changes in stiffness and in strength determine the load-bearing behaviour of the support system.

The full contribution of load bearing capacity of the initial lining over the operation time of the Diversion Tunnel cannot be considered due to the above mentioned influence and the combination of adverse effects. It is assumed that the initial lining may gradually loose its load-bearing capacity. It deforms and thus exerts stresses and strains on to the final lining.

This aging process of the initial lining is simulated by modelling a transition from a purely elastic to an elasto-plastic material behaviour. The analysis model takes into account a potential change of stiffness and strength of the initial lining over time due to

- corrosion/failure of the reinforcement,
- degradation, weathering of shotcrete,

A conservative approach according to the "Gray Rock Philosophy" [7] is selected: The initial lining is modelled elasto-plastic as part of the rock with adequate strength parameters. Tensile stresses are to be avoided. The modulus of elasticity is reduced.

4.6.3 Final Lining

The final lining is analysed for all permanent and temporary loads. The analysis is carried out under the assumption that the initial lining does not contribute to resist the superimposed loads and displacements.

4.7 Tunnel Lining Design

4.7.1 Concrete Design

The initial lining consisting of rock dowels, steel ribs, steel wire mesh and shotcrete is checked against the design strength of concrete. In the calculation, the contribution of steel elements (reinforcement, dowels, ribs) to the bearing
capacity of the initial lining is ignored. The degree of safety of the lining \( (\alpha \) degree of mobilization of the strength of the unreinforced concrete) is expressed by checking the safety factor \( f_{NM} \), which is the ratio of the design normal force \( N_{sd} \) and the resisting normal force \( N_{rd} \), considering the calculated eccentricity \( e = M_{sd} / N_{sd} \) of the unreinforced shotcrete only.

The final lining consisting of cast-in-place concrete is checked against the factor \( f_{NM} \) in the same way as the initial lining.

The minimum safety factors \( f_{NM} \) are listed as calculation results in chapter 6.

The following formula is used for the design of unreinforced concrete:

\[
N_{rd} = \phi_c \cdot f_c' d \left(1 - 2 \frac{e}{d}\right)
\]

\( N_{rd} \) is the resisting normal force with \( b = 1 \text{ m} \)

\( d \ldots \text{thickness of the tunnel lining} \)

\( e \ldots \text{eccentricity} \) (\( e = M/N \))

The resistance factor of concrete \( \phi_c \) is assumed to be 0.60 according to CSA A23.3–94 [b]. The required design factor \( f_{NM} = N_{sd} / N_{rd} \) for design check of the lining is:

\( f_{NM} \geq 1. \)

Herein the computed structural forces \( N \) will be multiplied by a factor \( \alpha_L = 1.5 \) according to CSA A23.3 in order to get the design structural forces \( N_{sd} \).

In addition the maximum eccentricity is controlled by

\( e / h_w \leq 0.33. \)

\( h_w \) represents the structural height of the element.

4.7.2 Steel Design

Steel - if required - is designed according to CSA S16–01 [a].

4.7.3 Safety factors

The following factors of material resistance are selected:

- concrete \( \phi_c = 0.6 \)
steel $\phi_s = 0.9$

The load factors are generally selected in accordance with the Design Criteria, chapter 4.5.10. Reduced factors are applied solely for following extraordinary load cases:

a) short-term prestressing pressure for interface grouting with a load factor $\alpha_L = 1.0$ is in accordance with CSA A23.3–94 [b], since the grouting operations is carefully monitored and the pressure can be instantly controlled.

b) worst-case scenarios of a groundwater pressure on the lining (worst credible assumption as outlined in chapter 5.2.6) in combination with an unfrequent temporary operation state "Dewatering of Tunnel". Factors for such a load-combination "worst case – temporary state" have been assumed to be:

load factor $\alpha_L = 1.0$

resistance factor of concrete $\phi_c = 0.6$

In the detail design the load factor of 1.25 (instead of 1.0) will be used for external hydrostatic water pressure. (A design check proved the application of the load factor of 1.25 for external hydrostatic water pressure to be o.k.)
5

DESIGN BASIS

5.1 General

It has to be appreciated that, prior to tunnelling, tunnel design represents a prediction which is either verified on site to ensure, that all design assumptions are confirmed, or which has to be adjusted in-situ to suit actual conditions.

The initial steps of the tunnel design procedure are to collect geological data, then to establish geotechnical parameters in those sections along the tunnel profile with consistent characteristics and finally to summarize the geological series with similar mechanical properties.

Further, the boundary conditions such as virgin stresses, size, shape and orientation of the opening are taken into account in order to establish a possible failure mechanisms, thereby establishing the potential behaviour of the rock mass while the opening is excavated. Different failure mechanisms require different support measures and different models of analysis to design the support measures. In order to simplify procedures at the site, support types are established which apply to the various types of behaviour of rock mass as a result of excavation.

5.1.1 Geology

Twelve stratigraphic formations are identified in the project area. They consist of sequences of sedimentary rock of Ordovician to Devonian age. These are namely the Guelph, Lockport, De Cew, Rochester, Irondequoit, Reynales, Neahga, Grimsby, Power Glen, Whirlpool and Queenston formations. Some of these are only a few meters thick. Eleven of the mentioned formations are expected to occur along the tunnel structure. The uppermost Guelph formation will not intersect with the proposed tunnel alignment. The lithological spectrum of the encountered formation covers limestone, dolostone, sandstone and shale (see Design Basis and Method Statements [5] for details).

5.1.2 Calculation Sections

3 preliminary Finite Element Calculations were defined:

Calculations with Key Block Theory depend on the varying trend and plunge of the tunnel axis. The tunnel sections to be analysed by KeyBlockTheory are summarized in Chapter 5.2.8.

5.1.3 Groundwater

Three major groundwater flow regimes are encountered in the rock formations of the project area. The uppermost occurs in the Guelph, Lockport and De Cew formations. This aquifer is connected to the surface water and shows the highest permeability of the entire sequence. A second flow regime is associated with the low permeability strata of the Rochester, Neahga, Power Glen and Queenston formations, forming a system of aquitards. A third flow regime is associated with the deeper permeable strata of the Irondequoit, Reynales, Thorold, Grimsby, Whirlpool and upper Queenston formations. These strata form deep lying aquifers. Groundwater elevations are reported to vary significantly from strata to strata and from location to location. Some groundwater heads encountered showed artesian behaviour with pressure heads above ground elevation.

The following maximum groundwater levels (measured groundwater levels within the Queenston Formations as indicated in the GBR in determination of the external hydrostatic water pressure) are applied to the calculations with respect to the ranges of the groundwater level (see Design Basis and Method Statements [5] and Geotechnical Longitudinal Section (2) for details):

5.2 Input Parameters

Generally best estimate values for ground and lining properties are applied to the analysis. The effect of variation of the selected design values for these properties has been continuously checked by means of sensitivity analysis.

The range of parameters that is used to appreciate parameter variability in the design is defined in the GBR-A, “Required Response 3” [4].

5.2.1 In-Situ Stresses

In-situ stress conditions in southern Ontario are characterised by high horizontal stress, exceeding vertical stresses in parts significantly. The stress field is reported to be relatively consistent trending in a north-easterly direction. However, the magnitudes of stress and the direction of the maximum stress can vary significantly depending on lithology, depth and topographical features (see Design Basis and Method Statements [5] for details).

The in-situ stresses applied to the calculations are based on the Geotechnical Data Report [1] and are summarized in GBR-B [4] and in Design Basis and Method Statements [5]:

Table 6: In-Situ Stress Conditions (Stress Ratio: Horizontal Stresses / Vertical Stresses)

The vertical stresses are generally based on the full overburden gravity load of the rock mass. In situ testing showed that the vertical stresses are 30% above the calculated vertical stresses.

The above mentioned stress ratios are used to initialize the primary stress field within the FEm calculations. In case widespread plastic zones develop during initial state, either increase of vertical stress or decrease of horizontal stress has to be applied to the analysis in order to ensure stable initial conditions of the analysis model.

5.2.2 Rock Mass Strength & Stiffness Parameters

The rock mass parameters used in the analysis are based on table 6.16 of the Geotechnical Baseline Report [4].

The strength and deformation properties to be considered with the calculations are summarized for the proposal design in Table 7 below and will be updated in detail design.

Table 8: Additional Soil Strength & Stiffness Parameters

The strength parameters summarized in Tables 7 and 8 are considered as "peak-strength" data. According to the Owner's Mandatory Requirements [2] especially the Queenston shale exhibits a predominant "post-peak" behavior. The reduction from peak strength to post-peak strength is considered according to the Owner's Mandatory Requirements, chapter 8.3.4 [2]:

*The following parameters shall be used in the analysis:*

(iii) Hoek-Brown residual rock mass strength parameters: $mr = 1.0$, $sr = 0.001$

(or equivalent)

(iv) plastic shear strain in rock for peak to post-peak: ranging from 0.5% to 2.0%

Consequently the following "peak-" and "post-peak" strength parameters are applied to the Queenston formation (Table 9).

<table>
<thead>
<tr>
<th>Formation</th>
<th>Peak-Strength</th>

<td>1.8</td>
</tr>
<tr>
<td>Lower Queenston</td>
<td>33</td>
<td>2.8</td>
</tr>
</tbody>
</table>
Table 9: Strain Softening Strength Parameters for Queenston Shale

The decrease in strength due to strain softening is considered in the analysis with the mobilization of plastic shear strains during all calculation phases. As soon as a critical plastic shear strain will be reached in any zone, a post peak strength decrease to the residual strength will be executed. According to the Owner's Mandatory Requirements [2] the relevant plastic shear strain to reach a decrease to a residual strength is in the range of 0.5% to 2.0 %. Within the subsequent analysis, a best estimate value of 1.25 % is selected for the critical plastic shear strain. An elasto–brittle material model is used, i.e. a sudden decrease in post–peak strength is modeled as soon as the critical plastic shear strain is reached.

5.2.3 Bedding Plane Parameters

Sheared, weak bedding planes exist between many of the rock formations and within the Queenston Formation. Primary bedding planes are defined as major bedding planes between lithological units above the Queenston Formation and between subunits within the Queenston Formation. According to the geotechnical data available [1,4] six major stratigraphic divisions have been identified in the Queenston Formation, which are separated by fairly distinctive primary bedding planes.

It is expected that especially the primary bedding planes, which are present between the subunits of the Queenston Formation, affect the stresses and strains around the tunnel during and after excavation. In order to account for such discontinuous behaviour the following parameters based on test data given in the GDR [1] (Volume 2, Figure 12.1) are used for modelling the bedding planes (Table 10):

<table>
<thead>
<tr>
<th></th>
<th>Peak–Strength</th>
<th>Post–Peak–Strength</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>$\phi_{\text{peak}}$ [°]</td>
<td>$c_{\text{peak}}$ [MPa]</td>
</tr>
<tr>
<td>Formation</td>
<td></td>
<td></td>
</tr>
<tr>
<td>bedding planes between subunits of Queenston Shale</td>
<td>24</td>
<td>0.45</td>
</tr>
</tbody>
</table>
Table 10: Strength Parameters for bedding planes between subunits of Queenston Shale

Since no particular information is available so far, the relevant displacement within the bedding plane to trigger the decrease to residual strength is selected on the basis of engineering judgement. Within the subsequent analysis a best estimate value of 10 mm is selected for this critical displacement. The elasto-brittle material model is used (see chapter 5.2.2).

5.2.4 Long-term Behaviour

As already outlined in chapter 4.5.9 time dependent deformation phenomenon is described in terms of processes, which are interrelated: "rock squeeze" and "swelling".

5.2.4.1 Time-dependent deformations observed during previous constructions

**Vertical Shaft Wheel Pit:**

During the construction of the vertical shaft Wheel Pit of the Canadian Niagara and Toronto Power Plants the 5.5 m wide and 50 m deep slots an inward movement of both walls was recognized (total maximum inward movement of both walls over a 68-yr period was approx. 7 cm) [4]. The data shows a general trend of decreasing rate of rock movement with time. According to an additional study evaluated by Yolles [14] in 1991 the rock squeeze is expected to continue at the presently established rate of approximately 0.15 - 0.48 mm per year.

**12-m diameter Trial Enlargement**

According to the GBR [4] within a 12-m diameter Trial Enlargement in the Queenston Formation a pattern of on-going, very small creep movements were measured in the first few months after excavation (maximum 5 mm measured from 7 to 70 days following excavation).

**Diversion Tunnel No. 1 and 2**

Measurements during and after excavation recorded horizontal inward movements of up to 60 mm over a 6-month period in Tunnel 1 (vertical...
movement of the crown was significantly smaller). Most of the movement occurred immediately after installation of the instrument. According to [4] the creep movement appears to be a logarithmic function of time.

**Construction of the Queenston–Chippawa Canal 2**

The canal was constructed in the early 1950s. The excavations extend about 18 m into the Lockport/DeCew Formations. According to [4] elastic deformation at the top of the rock cut amounted to about 1 to 1.3 cm on the first lift, with an additional 1.3 to 1.8 cm closure immediately following final excavation. Small creep movements of up to 0.33 cm/yr were noted for the 2 years that measurements were taken [4].

**5.2.4.2 Back–Analyses of the Toronto Power Turbine Pit Excavation**

Appendix 01 provides computer plots of a FE-back–analysis of the vertical shaft of the Toronto Power Plant. The measurements of this excavation have been used to estimate deformations with respect to the excavation work itself and to distinguish between additional swelling deformations and long-term rock squeeze deformations.

This calculation indicates:

- Sequenced excavation and installation of the shaft:
  maximum horizontal displacements ~ 6 mm

- Due to stress release and water ingress a swelling strain in the order of 0.5 % is expected in a limited area around the Shaft Wheel Pit:
  maximum additional horizontal displacements ~ 10 mm

- Rock Creep has been modeled in agreement with the model assumption given in the chapter hereafter. The maximum creep-value of 1.5 has been applied to the calculation resulting in:
  maximum additional horizontal displacements ~ 18 mm

The total horizontal displacements of 35 mm (each side–wall) are in good agreement with the observations as reported in the previous chapter.

**5.2.4.3 Swelling Behaviour**

The swelling behaviour initiated due to the tunnel excavation is correlated to the decrease of the first invariant of the stress state (mean effective normal stress) \( \Pi \) {15}.
The primary stress state $\sigma_p$ will change to the secondary stress state $\sigma_s$. Due to the excavation the tunnel lining will deform and a relaxation of the surrounding rock may appear. According to (15) swelling behaviour may occur as soon as the first invariant of the secondary stress state stress $I_{1,s}$, will be smaller then the first invariant of the primary stress state $I_{1,p}$:

$$I_{1,s} < I_{1,p}$$

with:

$$I_{1,s} = \sigma_{x,s} + \sigma_{y,s} + \sigma_{z,s} \quad \text{and} \quad I_{1,p} = \sigma_{x,p} + \sigma_{y,p} + \sigma_{z,p}$$

Due to such a stress release ($I_{1,s} < I_{1,p}$) swelling strains $\delta_{sw}$ will develop. Under the assumption that the swelling potential during primary stress state has been already vanished, it can be stated that the swelling potential equals the difference of the strain invariant of the primary and secondary state $\Delta I_{1,s,sw}$

$$\Delta I_{1,s,sw} = I_{1,p} - I_{1,s}$$

with

$$I_{1,s,sw} = K_{sw} \frac{I_{1,s}(1-\nu)}{\sigma_0(1-\nu)}$$

The subsequent FE-calculations indicate that the area with swelling potential according to the above mentioned criteria ($I_{1,s} < I_{1,p}$) is small. The reason in this regard is based on the advantages of the proposed lining system.

In addition a suppression pressure of $> 5$ MPa exists due to the high in-situ stresses - especially in horizontal direction. The sedimentary rock has anisotropic stress and strain behaviour. It has to be mentioned, that according to test results reported in [4] application of stress in one direction not only suppresses the swelling in that direction but also reduces the swelling in the orthogonal direction.

It can be concluded that the swelling potential is negligible on the one hand due to the expected secondary stress state and on the other hand due to the proposed excavation method and double shell lining system.

5.2.4.4 Rock Squeeze Behaviour

A time related approach to estimate "rock squeeze" or "rock creep" phenomena as described in Chapter 4.5.9 is used to estimate potential long-term stress-increase on the tunnel lining:
\[ E_{\text{rock}}(t) = \frac{E_{\text{rock}}(t = 0)}{1 + \varphi(t)} \]

The long-term rockmass behaviour is taken into account by calculating a reduced stiffness modulus \(E_{\text{rock}}(t)\) for the time \(t\), \(\varphi(t)\) represents the so-called creep-value. The long-term rock squeeze behaviour is simulated using a creep-value in the range of 0.5 to 1.5 for the time \(t = 90\) years. The range for \(\varphi(t = 90)\) years is selected on the basis of conservative engineering judgement. The maximum creep rate \(\varphi_{\text{max}} = 1.5\) has been evaluated on the basis of measurements of an existing structure (Wheel Pit back-analysis).

5.2.5 Interface Grouting Properties

The objective of the interface grouting is to lock into the lining a compressive strain greater than the tensile strain expected after filling the tunnel with water. This will prevent the development of tensile stresses in the lining and therefore avoid cracking during operation.

Prior to filling the tunnel and after grouting, the lining is highly compressed. These short-term grouting pressure will consequently decrease due to creep and shrinkage before filling the tunnel. Together with temperature decrease (cooling of concrete) these effects add up to the long-term grouting pressures to be applied.

Calculations are carried out:

- to estimate required long-term grouting pressures in order to avoid final tensile stresses in the tunnel final lining,
- to estimate compressive strain losses due to creep, shrinkage and temperature changes,
- to finally define the required short-term grouting pressures (without exceeding the allowable compressive strength of concrete).

The grouting pressure is assumed to be uniformly distributed within the grouting interface. Local deviations from this are largely unpredictable, but can be controlled during the carefully monitored Interface Grouting Operation.
5.2.6 Water Pressure

The applicable "Internal water pressure" is shown in the geotechnical longitudinal section (2) and will be treated as basis for subsequent analysis.

The high pressure interface grouting is designed to prestress the final concrete lining and the surrounding rock in such a way, that

- internal water pressure does not cause cracking of the lining concrete and
- water seepage along the outside surface of the tunnel is prevented.

Therefore an "external water pressure" will be taken as the measured groundwater levels indicated in section 5.1.3 a regular load case.

5.2.7 Lining Properties and Lining Dimensions

Initial Lining:

Immediately after excavation "young" shotcrete properties (E = 7500 MN/m²) are applied in the analysis. For subsequent design stages properties for "old" shotcrete (E = 15000 MN/m²) are taken into account after the shotcrete has hardened sufficiently.

The lining shotcrete is initially subjected to radial and tangential stresses as a result of the interlocking mechanism with the ground. The transfer of tangential stresses is limited in case shear failure occurs. Either the failure of rock or the failure of shotcrete is theoretically possible, therefore the strength parameter associated with the weaker material is used as failure criterion for the interface.

The lining thickness and geometrical parameters are presented in the drawings (5), (6) and (7) for each Rock Support Type.

Final Lining:

The Concrete properties used for analysis are presented in chapter 4.4.5. The geometry of the typical cross section is presented in (3). Different thicknesses of final lining (600 mm and 700 mm) are proposed in (3), which depend on the stress level, the lining has to resist.

5.2.8 Discontinuity Orientation and Additional Parameters for Wedge Analysis

Discontinuity Orientation
Five major discontinuity sets are identified along the tunnel alignment including bedding planes and 4 joint sets. The table 11 lists the major discontinuity sets provided in the CBR A [3].

Size, Shape and Orientation of the Tunnel

The shape of the bored Diversion Tunnel is circular with a diameter of 14.44 m. Along the proposed tunnel alignment, the tunnel changes its orientation several times significantly. The trend of the tunnel axis represents the orientation with respect to North: The plunge of the tunnel axis represents the grade with respect to a horizontal plane. Both parameters are evaluated resulting in 6 tunnel sections with varying trend and plunge. The relevant tunnel sections are summarised in table 13.

Table 14: Discontinuity properties

5.3 Analysis Models

5.3.1 FE-Model

General:

The Finite Element (FE) Method is applied to consider the surrounding ground as a load carrying element and to take nonlinear ground parameters into account. The dimensions of the Finite Element mesh are selected in a way that effects of the excavation on the boundaries of the system can be excluded. The boundary conditions of the FE mesh are as follows: The ground surface is free to displace, the side surfaces have roller boundaries and the base is fixed.
The Finite Element Code PLAXIS is used for the computations. Verification of the selected elements, materials and methods are given in [3,4].

In general, the ground is modelled using the isotropic constitutive model of Mohr–Coulomb with linear elasticity and perfect plasticity. The Mohr–Coulomb model requires a total of five parameters:

- \( E \) – Young’s modulus
- \( \nu \) – Poisson’s ratio
- \( \phi \) – friction angle
- \( c \) – cohesion
- \( \psi \) – dilatancy angle

Details of the constitutive model used are presented in [3].

**Stress Release ahead of face:**

The excavation of a tunnel is a three dimensional problem. As a result of excavation, deformations occur in the ground ahead the tunnel face. After excavation and initial lining application further deformations occur causing stresses in the shotcrete.

The stress release ahead of tunnel face is evaluated using preliminary 3D–FE analysis. The portion of forces acting on the ground ahead of excavation and the portion acting on the combined system of ground and lining depend on:

- Size of excavation
- Stiffness of ground
- Stiffness of the lining
- Unsupported length of excavation.

The stress analyses for the selected analysis sections are performed with 2D–FE models (i.e. plane strain analysis). In the 2D–analysis it is necessary to consider deformations of the ground, ahead of excavation (i.e. to approximate the load sharing effect). To evaluate the stress release of the ground in front of the tunnel face, the so-called \( \beta \)-method is used in the numerical analysis. The initial stress \( p_i \), acting around the tunnel excavation is divided into a part \( \beta_i \), \( p_i \), that is applied to the unsupported tunnel ahead of the face and a part \((1-\beta_i) \ p_i \), that is applied to the supported tunnel (see Figure 3). The factor \( \beta_i \) represents the stress release factor.
When simulating the excavation sequence of a tunnel, the finite elements within the excavation area are deactivated and equivalent lining forces (nodal forces) are analyzed to find a comparable initial stress state $p_i$. Equivalent nodal forces ($F_i$) act on the boundaries of the excavation and equilibrium conditions are not disturbed. In the first calculation phase, the equivalent pressure is reduced stepwise to the stress release value $\beta_i F_i$ (see Figure 2, Section B-B). In a second calculation phase, the remaining out-of-balance stress $(1-\beta_i) F_i$ is applied (lining installation) to the tunnel support (see Figure 2, Section A-A).

![Diagram of stress release phases]

Figure 2: Calculation phases simulating stress release

The stress release in front of the tunnel face is determined on the basis of comparison with preliminary 3D-FE calculations. In addition information of literature [2] is used.

### 5.3.2 Beam–Spring Model

An elastic beam–spring model is used for certain aspects of the design of the final lining. As indicated in the analysis assumptions for the Diversion Tunnel (see flow-chart, Fig. 1), the influence of:

- maximum short-term grouting pressure,
- shrinkage and creep,
- temperature change on the final lining concrete,
is analysed. Ultimate limit state and serviceability limit state analysis is carried out.

Linear elastic beam elements are used to model the lining. The subgrade reaction is represented by radial springs are following the tension cut-off criterion. Due to a waterproofing membrane between the initial lining and the final lining, tangential springs can be ignored.

Also the analysis of a “loosened slab of a thickness not less than 3 m” as rock load for the initial lining is analysed using a Beam Spring Model.

5.3.3 Key Block Theory

The potential influence of discontinuities on the excavation of the Diversion Tunnel is analysed by the program code “Unwedge”.

Unwedge \(6\) is a 3D stability analysis and visualization program for underground excavation in rock containing intersecting structural discontinuities using block theory \(5\). Safety factors are calculated for potentially unstable wedges and support requirements can be modeled using pattern bolting or spot bolting and shotcrete. Unwedge determines all possible wedges that can be formed by the intersection of 3 joint planes and the excavation. A maximum of 8 wedges is formed around the opening, but less than 8 wedges may be formed depending on the joint orientation and the shape and orientation of the excavation. Unwedge also determines the wedges that can be formed at both “ends” of the excavation.

The following failure modes can occur:

1. Falling or lifting
2. Sliding on a single plane
3. Sliding on two planes, along the line of intersection

The analysis is based on the assumption, that the wedges, defined by three intersecting discontinuities, are subjected to gravitational loading only. Stresses in the rock mass result in a confinement of rock blocks for which reason the chosen assumption is conservative. This means that the stresses on the joint planes are a result of self-weight of each wedge (as well as support forces, water pressure, seismic forces etc). While this assumption leads to some inaccuracy in the analysis, the error is generally conservative, leading to a reduced factor of
safety. However, the 3.005 version of the software enables to include the effect of in-situ stress on the wedges. But the inclusion of the Field Stress can only increase the factor of safety, it cannot be reduced the factor of safety. Field stress is therefore not considered for the analysis.

Water pressure is not considered for the analysis too.

The following important limitations and assumptions have to be kept in mind for interpretation of the analysis results:

- Unwedge is used to analyze wedge failure around excavations constructed in hard rock, where discontinuities are persistent, and where stress induced failure does not occur. It is assumed that displacements take place at the discontinuities, and that the wedges move as rigid bodies with no internal deformation or cracking.

- All of the discontinuity surfaces are assumed to be perfectly plane.

- Discontinuity surfaces are assumed to be persistent and extend through the volume of interest, therefore the discontinuities defining the wedge do not terminate in the region where the wedges are formed. The implication is, that no new cracks are formed in the analysis to allow wedge movement.

- The discontinuities are considered to be ubiquitous: in other words, they can occur at any location in the rock mass.

- The underground excavation is assumed to have a constant cross section along its axis.

- A maximum of three structural planes can be analyzed at one time. If more than three major planes are identified for the analysis of the structural data, then all combinations of these planes should be considered.

5.3.4 Convergence-Confinement Method

The convergence-confinement method is based on a concept that involves analysis of the ground structure interaction by an independent study of the behaviour of the ground and of the tunnel support. The ground behaviour is represented by a ground-reaction curve and the tunnel support is represented by a support reaction curve. The support pressure is evaluated from
canputations of the initial lining characteristics including shotcrete, steel ribs and anchors.

This method allows to estimate the load imposed on the support installed in the tunnel. When a section of support is installed in the immediate vicinity of the tunnel face, it does not carry the full load as a part of the load that is redistributed around the excavation is carried by the rock forming tunnel face. With great distance to the tunnel face, this so-called face-effect decreases and the support carries a greater proportion of the ground load. When the excavation face has moved well away from the section considered, the initial support carries the full design load.

The method applied in the convergence confinement calculations is based on literature \{8,9\} and is particularly used for:

1) preliminary tunnel support design
2) time-dependent load distribution of ground load to the initial support (short-term)
3) time-dependent load distribution of ground load to the final lining (long-term)

(1) is used before starting decisive stress analysis, (2) is applied to analyse load assumptions for FE-calculations as indicated in table 15 and (3) is applied to estimate the long-term stress increase due to rock-squeeze on the final lining.

Time-dependent behaviour is incorporated into the convergence-confinement method based on the literature \{10, 11\}.

5.4 Load Assumptions

Ground loads are defined depending on the following structural models:

5.4.1 Finite Element Model:

The initial lining is stressed as a result of tunnel excavation and it is deformed depending on the primary stress state, the strength and the stiffness of the rock mass. The continuum finite element model is used for the design of the tunnel initial support and the design of the final support. The following load cases are considered within the 2D calculations (Table 15):
<table>

</tbody>
</table>

Table 15: Relevant Load Cases for the FE-Calculations
The loads presented in the individual load cases are subsequently added up.

Only the loads "a" and "b" of load case 9 are calculated separately.

Load case 10 covers in fact the loads of load case 1 to 6, which are applied on a system model including a shear zone within the tunnel section and added up. In this calculation the loads of load cases 7 to 9 are not applied, since those loads are not decisive as shown by the load combinations of the standard case.
Standard Load Cases

1) Insitu stress state
\[ \sigma_0 = \alpha \cdot \gamma \cdot H \]
\[ \sigma_{in} = k_i \cdot \sigma_i \]
\[ \alpha \ldots \text{overconsolidation factor} \]

2) Stress release in front of excavation face
\[ F_i' = F_i (1 - \beta_i) \]
\[ \beta_i \ldots \text{stress release factor} \]
(determined from preliminary 3D-calculation)

3) Excavation, lining installation
\[ E_{\text{right}} = f (t, E_{\text{rock}}, E_{\text{lin}}) \]
a) girder 4m behind face \[ F_i' = F_i (1 - \beta_i) \beta_i \]
b) young shotcrete 20m behind face \[ F_i' = F_i (1 - \beta_i) \beta_i \]
c) old shotcrete \[ F_i' = F_i (1 - \beta_i) \beta_i \]
\[ \beta_{ij} \ldots \text{load transfer factors} \]
(determined from convergence-confinement analyses)

4) Final lining installation

5) Grouting pressure
\[ p_{\text{grout}} \]
- long term grouting pressure
(short-term grouting pressure checked by beam-spring model)

6) Internal water pressure
\[ p_i \]
- internal water pressure \( p_i \)

Figure 3: Calculation Phases "Standard Load Cases"
Additional Load Scenarios

7) external water pressure on lining

8) dewatering of tunnel

9a) "rock squeeze" assumption 1

\[ \sigma_v = \alpha_v \cdot \gamma \cdot H \]

\[ \sigma_r = k_r \cdot \sigma_v \]

- additional radial stresses due to rock squeeze phenomena (constant stress ratio)

9b) "rock squeeze" assumption 2

\[ \delta_h \]

- additional horizontal stresses due to tectonical movement (increasing stress ratio)

10) discontinuity analysis

"strong discontinuity" within tunnel section
5.4.2 Beam–Spring Model

The following loads have been determined for the subsequent calculations:

Rock loads:

A loosened rock slab of 3 m thickness up to the full width of the tunnel and shear deformations along bedding plane is analysed.

Grouting Pressure:

Short-term grouting pressures according to the assumptions indicated in Chapter 5.2.5 are analysed.

Temperature

With respect to temperature changes during and after filling of the tunnel with water, thermal strains are activated in the final lining. The applied maximum temperature gradients within the final lining are summarized in Table 2. To facilitate analysis the temperature changes are split in two parts:

- constant temperature change $T_{\text{const}}$
- temperature gradient $\Delta T$

<table>
<thead>
<tr>
<th></th>
<th>before watering up</th>
<th>after watering up</th>
</tr>
</thead>
<tbody>
<tr>
<td>constant temperature change $T_{\text{const}}$</td>
<td>+5</td>
<td>-3</td>
</tr>
<tr>
<td>temperature gradient $\Delta T$</td>
<td>+10</td>
<td>-6</td>
</tr>
</tbody>
</table>

Table 16: Thermal Forces

In the analysis it is assumed that an initial constant temperature of 10°C.

Concrete Shrinkage

A concrete shrinkage strain of $\varepsilon_s = -15.7 \times 10^{-5}$ is applied to the analysis (see Chapter 4.5.7).

Concrete Creep
A reduction of young's Modulus for concrete of 50% is assumed for the analysis (see Chapter 4.5.8).

5.4.3 Wedge Analysis:

The rock loads are determined by the geometry of rock blocks, which are formed by sets of discontinuities.

5.4.4 Convergence–Confinement Method

In–Situ Stress Field:

The stress field assumed for analysis is in accordance with the vertical stresses for full overburden and with the high horizontal stresses, which are anticipated (see Chapter 5.2.1).

Long–term Stress Field:

The long–term stress increase on the final lining due to rock–squeeze is considered in accordance with the assumptions given in Chapter 5.3.4.
6 DESIGN ANALYSIS RESULTS

6.1 General

[Results in this section were developed for the proposal design and are included for information only. Appendices referenced in this section have been intentionally removed. The analyses in this section will be updated in detail design.]

6.2 FE-Analysis

6.2.1 General

The FE-calculations were performed using the following units:

Length: m
Force: kN
Deformations: mm

The main input and output data are given in the Appendices. In all of the results, compressive stresses and forces were taken to be negative, whereas tensile stresses and forces were taken to be positive.

6.2.2 3D FE-Calculations

The stress release ahead of tunnel face is determined on the basis of preliminary 3D-FE calculations.

Two calculations have been carried out:

<table>
<thead>
<tr>

</tbody>
</table>

Table 17: Model Assumptions for 3D-FE Calculations

Following excavation steps have been applied:
• In-situ stress state
• Excavation (advance length 4 m)
• Installation of lattice girders 4 m behind tunnel face
• Young shotcrete 20 m behind tunnel face

Equivalent 2D model have been created in order to fit pre-convergence (i.e. stress release) and load factors for loading of temporary support. The results are summarized in following Table 18:

<table>

Table 19: Model Assumptions for 2D-FE Calculations – Proposed Alignment

The computer plots are attached to the Appendices 11 to 15.

The typical plots consist of:

1) Model Geometry
2) Longitudinal Section
3) Virgin Stress Field
4) Stress Release
5) Secondary Stress State – Initial Lining Installation
6) Long – Term Grouting Pressure (Distribution)
7) Grouting Chart (Grouting Design)

Additional calculations were performed to check:

8) Internal Water Pressure (Distribution)
9) Initialisation Ground Water Pressure
10) Tunnel Dewatering

For calculation sections close to existing structures additional plots are provided in order to check changes in stress state:

11) Comparison of stress state before / after excavation of the new Diversion Tunnel
Within 2 calculations (Section C/1 and F) the rock-squeeze effect has been analysed additionally:

12) "Rock Squeeze Effect" – Ground Reaction Curves
13) Rock Squeeze – Calculation Assumption 1
14) Rock Squeeze – Calculation Assumption 2

6.3 Beam-Spring Model

Linear elastic analyses are adequate for static loading of the tunnel lining from self weight, geo- hydrostatic, temperature, shrinkage, and live loads. The calculations result from a radial, elastic beam element method.

6.3.1 Geometry

The cross section of the tunnel is illustrated in (4). The outer diameter is 14.44 m, the shotcrete lining has a thickness up to 30 cm and the final lining thickness is 60 – 70 cm. For the subsequent calculations a representative tunnel diameter for the beam elements of 13.1 m has been assumed for modelling the final lining and respectively a tunnel diameter of 14 m for the initial support.

6.3.2 Performed Calculations and Calculation Parameters

The calculation parameters for the surrounding rock are in accordance with Chapter 5.2.2.

The ground reaction is taken into account by using an elastic-plastic subgrade reaction \( K \) (radial springs with tension cut-off criterion). Due to a waterproofing system between the initial support and final lining, tangential springs can be ignored.

The modulus of subgrade reaction \( K_R \) is calculated using the following formula:

\[
K_R = \frac{E}{R}
\]

For the following calculations short term grouting pressure is considered.

Table 27: Initial Support Calculation: “3 m slab”

6.3.3 Results

Short–Term Grouting Pressure

The detailed results, plots and listings, are shown in the Appendix 04. The most important results are summarized hereafter. The safety factor for the short–term grouting pressure has been adopted as indicated in Chapter 4.7.3 (load factor $\alpha_L = 1.0$ and resistance factor concrete $\Phi_c = 0.7$). The design check requires a design factor $f_{NM} \geq 1.0$.
Table 28: Results for short-term grouting

The calculation results indicate that the maximum short-term grouting pressure on a 60 cm final lining has to be restricted with 1.4 MPa. Increasing the thickness to 70 cm allows a maximum short-term grouting pressure of 1.7 MPa. The required maximum grouting pressure of 2.15 MPa for the calculation section below St. David Gorge) can be reached assuming a higher compressive strength $f_c\prime$ of the concrete. The above results consider a conservative compressive strength $f_c\prime = 27.5$ MPa (see Chapter 4.4.5). Assuming a compressive strength $f_c\prime$ of 35 MPa (incorporating an E-modulus of 27 GPa) allows to pre-stress the 70 cm thick final lining with maximum 2.2 MPa grouting pressure.

Constrained Forces

The detailed results, plots and listings, are shown in the Appendix 05. Short term grouting pressure (1.25 MPa assumed) in combination with thermal forces, shrinkage and creep as described in chapter 4.5 result in:

Table 29: Results for Constrained Forces

<table>
<thead>
<tr>
<th>Calculation</th>
<th>radial deformation [mm]</th>
<th>factor of safety $f_{NM}$ [ ]</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>7.5</td>
<td>1.7</td>
</tr>
</tbody>
</table>
The evaluation of the ratio between applied short-term grouting pressure and resulting long-term grouting pressure depends mainly on the influence of creep, shrinkage and temperature (see Chapter 5.2.5). Compressive strain losses due to these factors are summarized in the Table 30 below:

<table>
<thead>
<tr>
<th>calculation</th>
<th>relative radial shortening [mm]</th>
<th>relative radial shortening [%]</th>
</tr>
</thead>
<tbody>
<tr>
<td>temperature</td>
<td>0.197</td>
<td>0.03</td>
</tr>
<tr>
<td>shrinkage</td>
<td>1.028</td>
<td>0.157</td>
</tr>
<tr>
<td>creep</td>
<td>3.109</td>
<td>0.47</td>
</tr>
</tbody>
</table>

Table 30: Expected Radial shortening due to Shrinkage, Creep and Temperature

The design of required short-term grouting pressure is attached to the Appendices of the FE-calculations. These grouting charts consider a loss due to creep and temperature of maximum 0.5 % (radial shortening). Herein it is assumed that the influence due to shrinkage, i.e. migration of excessive water from the interior of the concrete mass, has been taken place before grouting.

"3m slab" on initial support

The calculations proof that a rock load due to a “3m slab” as defined in Chapter 5.4.2 can be supported by one of the subsequent initial support elements (The detailed results see below and in Appendix 06):

\[ \varepsilon (2\text{m}) = 9.5 \text{ kN} \]
6.4 Wedge Analysis

For the analysis of the results the following simplifications was adopted:

Combinations of the four major joint sets resulted in unrealistic high and narrow wedges due to their steep dip angle. Downsizing them to a realistic height of a few meters resulted in unrealistic thin, needle like wedges. Truncation of the wedges by a forth plane (bedding plane) a few meters above the wedge base is not supported by the software. Therefore it is assumed that wedges formed by discontinuity combinations including the bedding plane also cover those truncated wedges in size, weight and position.

The analysis of the 60 possible combinations considering all major discontinuity sets and the change of the tunnel orientation along the alignment resulted in 87 potentially unstable wedges (not considering unrealistic high wedges). Table 32 shows one example for the block stability analysis carried out for the tunnel section below St. David’s Gorge.

Table 32: Example for wedge analysis

The below table 33 lists all potentially unstable wedges identified for the Niagara Tunnel Facility Project.

Table 33: Results of the wedge analysis

In order to evaluate the support requirements for each tunnel section concerning block failure the proposed support classes were applied on all blocks of each section. Support was increased till a factor of safety >1 was reached. The analyses were carried for support categories 2 to 4, which are applicable for support of block failure. For the analyses only rock bolts were considered since it is planned that shotcrete is going to be applied some distance behind the TBM. Therefore the bolts have to be able to take the full load of the blocks. Face blocks were not considered in the analyses.

The results show that in general support categories 2 to 4 are sufficient to support all rock loads produced by block failure. Restrictively it has to be mentioned that few blocks could no be adequately supported by pattern bolting due to their elongated shape and/or small size. Those few blocks will require additional spot bolting.

The following table 34 summarizes the results of the support analyses considering block failure.

ILF CONSULTING ENGINEERS

T:\pr09\921_Niagara_Tunnel\docs\status_analysis_final.doc
7 CONCLUSIONS

A double shell lining system consisting of an initial support and a final lining (cast in place) separated by a waterproofing system has been investigated. The waterproofing membrane system prevents seepage between inside and outside of the Diversion Tunnel and acts as a suitable corrosion protection for the final lining. The final lining will be installed once tunnel excavation is completed. High pressure interface grouting prevents tensile stresses mobilized through internal water pressure. Thus cracking of the lining concrete is avoided and water seepage along the outside surface of the tunnel is prevented.

Using a comprehensive stress analysis it has been proven that the proposed tunnel lining system is capable of adequately supporting all loads including those imparted on the lining from long-term effects.

DEWATERING SHAFT SYSTEM

5 dewatering shafts will be located on the centreline of the tunnel at approx. km 8.9 measured from the intake of the Diversion Tunnel such that the Owner’s pumping equipment can be lowered into the tunnel. Each shaft is circular and drilled with a minimum diameter of 1.05 m in overburden and 0.915 m in rock to accommodate a min. 750 mm steel pipe as shown on the Proposal Drawings. The annulus around the pipe is grouted to prevent water seepage between different geological formations along the outside of the pipe.

GEOLOGY

Twelve stratigraphic formations are identified in the project area. They consist of sequences of sedimentary rock of Ordovician to Devonian age. These are namely the Guelph, Lockport, Do Cew, Rochester, Irondequoit, Reynales, Neahga, Grimsby, Power Glen, Whirlpool and Queenston formations. Some of these formations are only a few meters thick. The shafts intersect eleven of the geological formations. The uppermost Guelph formation will not be affected by the construction of dewatering shafts. The lithological spectrum of the encountered formation covers limestone, dolostone, sandstone and shale (see chapter 3 of [5] for details).

GEOTECHNICAL INPUT PARAMETERS

The input parameters used in the analysis are in accordance with the evaluated calculation parameters included in the "Structural Design Analysis for the Diversion Tunnel" [6].
6 GROUNDWATER

Three major groundwater flow regimes are encountered in the rock formations of the project area. The uppermost occurs in the Lockport and De Cew formations. This aquifer is connected to the surface water and shows the highest permeability of the entire sequence. A second flow regime is associated with the low permeability strata of the Rochester, Neahga, Power Glen and Queenston formations, forming a system of aquitards. A third flow regime is associated with the deeper permeable strata of the Irondequoit, Reinales, Thorold, Grimsby, Whirlpool and upper Queenston formations. These strata form deep lying aquifers. Groundwater elevations are reported to vary significantly from stratum to stratum and from location to location. Some groundwater heads encountered showed artesic behaviour with pressure heads above ground elevation.

7 EXCAVATION METHOD AND SUPPORT MEASURES

The dewatering shafts are drilled by raiseboring technique. In the overburden soil, large diameter holes are bored and supported by steel casing. For each shaft a pilot bore is lowered through the rock formations into the Diversion Tunnel. There a cutter head of suitable size is mounted on the drill rod and lifted to enlarge the pilot hole in upwards direction. The borehole section through the rock formations is considered to be stable without support until raiseboring is finished, the steel pipe installed for permanent support and the annulus filled with mortar grout.

8 CALCULATION MODEL

8.1 Design Loads

8.1.1 Structural and Dead Loads

Dead load of structural and non-structural elements is based on unit weight and computed volume of the materials. The following unit weights are used:

- Unreinforced Concrete: 24.0 kN/m³
- Structural Steel: 78.5 kN/m³
- Rock / Soil: see [6]
- Water: 10.0 kN/m³
8.1.2 Hydrostatic Pressure

It has to be distinguished between the internal hydrostatic pressure and the external ground water pressure.

The applicable "internal water pressure" and "external water pressure" are shown in the geotechnical longitudinal section (2) and will be treated as basis for subsequent analysis.

8.1.3 Seismic Loads

Underground structures are generally less sensitive to seismic effects than surface structures, therefore no seismic loads are considered for preliminary design. At detail design stage a seismic analysis based on actual data will be carried out.

8.1.4 Long-term Rock Squeeze

8.1.4.1 Time Dependent Deformation Behaviour

It has to be emphasized that a time dependent deformation phenomenon is assumed for the Niagara area and described as "rock squeeze" and "swelling". It is well recognized that these processes are interrelated, and the individual effects of each are difficult to distinguish. Both effects can continue for many years [4].

Squeeze is usually associated with the long-term creep behaviour of rock, initiated by the relief of high in situ horizontal stresses. There is a well documented history of rock 'squeeze' affecting surface excavations in the upper dolostones and dolomitic limestones. This squeeze, however, may include the effects of swelling of the shale interbeds in these rock units [4].

8.1.4.2 Swelling Behaviour

Swelling to be assumed for design purposes in the Queenston Formation is given in the Owner's Mandatory Requirements [2]. There is no available data regarding suppression of swell potential for the other formations.

Generally swelling involves a volume increase and is initiated by the relief of the high in situ stresses. However, swelling also requires the presence of fresh water. The process is associated with ionic diffusion of salts from the connate pore water in the rock. The swelling phenomenon can be suppressed under applied stresses.

For swelling to occur, the necessary conditions are:

- the relief of initial stresses, which serves as an initiating mechanism,
- the accessibility to fresh water.
an outward salt concentration gradient from the pore fluid of the rock to the ambient fluid.

According to the Owner's Mandatory Requirements [2] a maximum swelling pressure of 5 MPa has to be applied to the calculations.

8.1.4.3 Rock Squeeze Behaviour

The rock expansion upon unloading observed in previous constructions [4] is not necessarily associated with the swelling of clay minerals, although in the presence of swelling clay minerals the time dependent deformation is generally greater.

Rock squeeze is defined as substantial time-dependent deformation in the vicinity of the tunnel as a result of load introduced by redistribution of stresses adjacent to the excavated tunnel.

8.1.5 Load Combinations

For load combinations not including earthquake, factored loads are determined in accordance with CSA S16-01 [a]. Herein the effect due to specified loads is multiplied by a load factor $\alpha$. A load combination factor $\psi$ and an importance factor $\gamma$ is also considered:

$$\alpha_i \cdot D + \gamma \psi (\alpha_i \cdot L + \alpha_i \cdot T)$$

where

- Load factors $\alpha$ for:
  - Dead loads: $\alpha_i = 1.25$
  - Live loads: $\alpha_i = 1.5$
  - Temperature loads: $\alpha_i = 1.25$

- Load combination factor $\psi$:
  - $\psi = 1.00$ when L or T is considered
  - $\psi = 0.7$ when a combination of L and T is considered

The importance factor is equal to 1.0 for all load combinations.
8.2 Shaft Design

8.2.1 Steel Design

Steel is designed according to CSA S16-01 [a]:

- stress analysis with \( \sigma f = (\alpha, N) / A \)
- max. allowable unfactored radial pressure:
  \[ P_r = \frac{E}{4(1-v^2)} \frac{s^3}{r^3} \]
  where
  - \( s \) ... required wall thickness [mm]
  - \( r \) ... radius of pipe, [mm]
  - \( E \) ... modulus of elasticity [N/mm²]
  - \( v \) ... Poisson's ratio
- allowable factored radial pressure: \( p_r = p_r / \phi_f \)

8.2.2 Design of Annular Grout

For loads not associated with water pressure, the annular grout ring is considered to contribute to the load bearing capacity of the shaft structures in addition to the steel pipes. Similar to unreinforced concrete, the safety factor \( f_{u,r} \) is used for the assessment of load bearing contribution of the annular grouting mortar. \( f_{u,r} \) is the ratio of the design normal force \( N_{u,a} \) and the resisting normal force \( N_{u,r} \), considering the calculated eccentricity \( e = M_{u,a} / N_{u,a} \) of load reaction forces in the grouting mortar.

The minimum safety factors \( f_{u,r} \) are listed as calculation results in chapter 5.

The following formula is used for the design:

\[ N_{u,a} = \phi_f \cdot f_{u,r} \cdot d \left( 1 - \frac{e}{d} \right) \]

\( N_{u,a} \) is the resisting normal force with:
- \( b = 1 \) m
- \( d \) ... thickness of annular grout
- \( e \) ... eccentricity \( e = M_{u,a} / N_{u,a} \)

The resistance factor of concrete \( \Phi \) is assumed to be 0.60 according to CSA A23.3-94 [b].

The required design factor \( f_{u,r} = N_{u,a} / N_{u,r} \) for design check of the lining is:

\[ f_{u,r} \geq 1 \]

Herein the computed structural forces \( N \) will be multiplied by the factor \( \mu = 1.5 \) according to CSA A16.6-04 [a] in order to get the design structural forces \( N \).
In addition the maximum eccentricity is controlled by

\[ e / h_s \leq 0.33 \]

\( h_s \) represents the structural height of the annular ring.

### 8.2.3 Safety factors

The following factors of material resistance are selected:

- Concrete \( \Phi_1 = 0.6 \)
- Steel \( \Phi_2 = 0.9 \)
- Buckling \( \Phi_3 = 2.5 \)

The load factors are generally \( \alpha = 1.5 \) according to CSA A16-01 [a]. Reduced factors are applied solely for following extraordinary load case:

a) worst-case scenarios of a groundwater pressure or a swelling pressure on the lining in combination with an unfrequent temporary operation state “Dewatering of Tunnel”

Factors for such a load-combination “worst case – temporary state” have been assumed to be

\[ \alpha = 1.0 \]

### 9 DESIGN ANALYSIS RESULTS

Linear elastic analyses are adequate for static loading of the tunnel lining from self weight, geohydrostatic, temperature, shrinkage, and live loads.

#### 9.1.1 Geometry

The cross section of the shaft is illustrated in (4). The inner diameter is 0.75 m.

#### 9.1.2 Performed Calculations and Results

The following load cases are considered. The detailed results, plots and listings, are shown in the Appendices.
<table>

Table 1: Results of Calculations

The Steel Lining of the shaft has to be constructed with a thickness of minimum 20 mm in the upper Geological Formations (Overburden and Lockport). Within the Queenston Formation the wall thickness has to be increased to 30 mm.

**CONCLUSIONS**

The structural design analysis has proven that the proposed shaft lining system is capable of adequately supporting all loads including those imparted on the lining from long term effects.
Appendix 1: Calculations
1) Swelling in Quenza — Worst case scenario: $N = \frac{P \cdot r}{A}$, $A = L \cdot t$ = 1000 mm

Axial force: $N = \frac{P \cdot r}{A} = \frac{5000 \text{KN}}{0.8 \times 420 \times 1000} = 0.88 \text{mm}$

2) Swelling in Quenza + Internal Water Pressure: $N = \frac{P_{\text{sw}} + P_{\text{wp}}}{A}$, $r = 0.8 \times 0.275 = 1.35 \text{KN}$

Axial force: $N = \frac{P_{\text{sw}} + P_{\text{wp}}}{A} = \frac{5 - (4) \times 0.275}{0.8 \times 420 \times 1000} = 0.57 \text{mm}$

3) Swelling in Lock Port — Worst case scenario: $P_{\text{sw}} = 2.5 \text{KN}$, $A = L \cdot t$

Axial force: $N = \frac{P_{\text{sw}} \cdot r}{A} = \frac{2.5 \times 0.275}{0.8 \times 420 \times 1000} = 3.375 \times 10^{-6} \text{KN}$

$\phi = \frac{N \cdot r}{A} = \frac{3.375 \times 10^{-6} \times 1.0}{0.8 \times 420 \times 1000} = 2.48 \text{mm}$
4) Swelling in bore: \( P_{sw} + P_{wp} = 0.5 \text{ atm} \) \( d = 7.5 \) mm

\[ \sigma_f = \frac{k \times d}{l} \]

\[ l = 6 \times 10^3 \text{ mm} \]

\[ f_{min} = \frac{k \times d^2}{6d \times 1000} = \frac{7.5 \times 7.5^2}{0.2 \times 4.2 \times 1000} = 2.71 \text{ mm} = 3.0 \text{ mm} \]

5) Internal water pressure

\[ P_{wp} = 0.4 \text{ atm} \]

\[ d = 15 \text{ mm} \]

\[ \sigma_f = \frac{k \times 15}{l} \]

\[ l = 6 \times 10^3 \text{ mm} \]

\[ f_{min} = \frac{k \times 15^2}{6 \times 10^3} = \frac{5.25 \times 15^2}{0.2 \times 4.2 \times 1000} = 2.58 \text{ mm} = 2.5 \text{ mm} \]

6) In situ stress, \( \sigma_h \) overestimation

\[ \sigma_h = \sigma_f \times k_e \]

\[ k_e = 4.5 \]

\[ \sigma_h = 2.5 \times 15^2 = 14.376 \text{ kN/m}^2 \]

Load pressure factor:

Steel pipe: Wall thickness \( \approx 25 \) mm

\[ E = 200 \text{ GPa} \]

Concrete:

\[ E = 25 \text{ GPa} \]
IG 21 CPD - Diversion Tunnel

Dewatering Shafts

Load split factor: \( \frac{25 \times 65}{57 \times 2.5} \approx 3.5 \)

Load carried out by grout: \( \frac{14978}{3.5} = 4278 \text{ kN/m}^2 \)

Load on the steel pipe: \( 14978 - 4278 = 10697 \text{ kN/m}^2 \)

Axial force: \( N = 4278 \times 0.575 = 4.4 \text{ kN} \)

\[ \delta = \frac{N \cdot 1000}{A} \]

\[ A = 5.5 \times 10^{-6} \times 1000 = 0.55 \text{ mm} 

\[ t_{min} = \frac{N \cdot 1000}{A \cdot 1000} = \frac{4278 \times 10^3 \times 1000}{0.55 \times 420 \times 1000} = 10.5 \text{ mm} = 11 \text{ mm} \]
BUCKLING OF CIRCULAR SHAPED MEMBERS:

\[ p_k = \frac{E \cdot s^3}{4 \cdot (1 - \nu^2) \cdot r^3} \]

Diameter: \( D = 760 \text{ mm} \)
Elastic modulus: \( E = 200000 \text{ N/mm}^2 \)
Poison constant: \( \nu = 0.3 \)
Required Wall Thickness: \( s = 23 \text{ mm} \)
Radius: \( r = 368.7 \text{ mm} \)
Safety Factor: \( \alpha_E = 2.5 \)

Unfactored Radial Pressure: \( p_k = 12.50 \text{ N/mm}^2 \)
Factored Radial Pressure: \( p_{af} = 5.00 \text{ N/mm}^2 \)
BUCKLING OF CIRCULAR SHAPED MEMBERS:

\[ p_K = \frac{E}{4(1-\nu^2)} \frac{s^3}{r^3} \]

Diameter: \( D = 760 \text{ mm} \)
Elastic modulus: \( E = 200000 \text{ N/mm}^2 \)
Poison constant: \( n = 0.3 \)
Required Wall Thickness: \( s = 23 \text{ mm} \)
Radius: \( r = 368.5 \text{ mm} \)
Safety Factor: \( \alpha_B = 2.5 \)

Unfactored Radial Pressure: \( p_x = 13.50 \text{ N/mm}^2 \)

Factored Radial Pressure: \( p_{fr} = 5.40 \text{ N/mm}^2 \)
BUCKLING OF CIRCULAR SHAPED MEMBERS:

\[ p_{k} = \frac{E \times s^3}{4 \times (1 - \nu^2) \times r^3} \]

- Diameter: \( D = 760 \text{ mm} \)
- Elastic modulus: \( E = 200000 \text{ N/mm}^2 \)
- Poison constant: \( \nu = 0.3 \)
- Required Wall Thickness: \( s = 18 \text{ mm} \)
- Radius: \( r = 371.0 \text{ mm} \)
- Safety Factor: \( \alpha_B = 2.5 \)

Unfactored Radial Pressure: \( p_r = 6.25 \text{ N/mm}^2 \)

Factored Radial Pressure: \( p_a = 2.50 \text{ N/mm}^2 \)
BUCKLING OF CIRCULAR SHAPED MEMBERS:

\[ p_k = \frac{E}{4 \times (1 - v^2)} \times \frac{s^3}{r^3} \]

Diameter: \( D = 760 \text{ mm} \)
Elastic modulus: \( E = 200000 \text{ N/mm}^2 \)
Poison constant: \( n = 0.3 \)
Required Wall Thickness: \( s = 19 \text{ mm} \)
Radius: \( r = 370.5 \text{ mm} \)
Safety Factor: \( \alpha_B = 2.5 \)

Unfactored Radial Pressure: \( p_u = 7.50 \text{ N/mm}^2 \)
Factored Radial Pressure: \( p_{af} = 3.00 \text{ N/mm}^2 \)
BUCKLING OF CIRCULAR SHAPED MEMBERS:

\[ P_K = \frac{E}{4(1 - \nu^2)} \cdot \frac{s^3}{r^3} \]

Diameter: \( D = 760 \text{ mm} \)
Elastic modulus: \( E = 200000 \text{ N/mm}^2 \)
Poison constant: \( \nu = 0.3 \)
Required Wall Thickness: \( s = 29 \text{ mm} \)
Radius: \( r = 365.6 \text{ mm} \)
Safety Factor: \( \alpha_b = 2.5 \)

Unfactored Radial Pressure: \( p_u = 26.74 \text{ N/mm}^2 \)
Factored Radial Pressure: \( p_{oa} = 10.70 \text{ N/mm}^2 \)

1 INTRODUCTION

This report provides the stability analysis for excavations including intake channel, outlet canal and the excavation for intake and outlet structure. Since all excavations are situated in the Lockport-DeCew-Rochester geological formations and identical parameters are therefore applicable, only the deepest excavation located at the outlet is analysed in detail.

2.3 Codes and Standards

3 CALCULATION SECTION

The deepest section close to the Diversion Tunnel is the excavation for the Outlet Structure. The slope has a total height of approx. 40 m. The excavation boundary for the outlet structure consists of a vertical wall of maximum 32 m height. This vertical wall ends with a berm at el 176 m followed by an inclined slope with approx. 8 m height.

4 GEOLOGY

The excavation for the Outlet Structure will be within four stratigraphic formations. They consist of overburden material and the sequences of sedimentary rock: Lockport, De Cew and Rochester.

5 GEOTECHNICAL INPUT PARAMETERS

5.1 Overburden Material

Following geotechnical parameters are applied for the overburden material (based on data presented in [4]):

\[ \gamma = 20 \text{ kN/m}^2 \]
\[ c = 20 \text{ kN/m}^2 \]
\[ \phi = 15^\circ \]

5.2 Rock Units

The rock mass parameters are based on the Geotechnical Baseline Report [4]. The strength properties to be expected are summarized in Table 1.

Table 1: Rock Mass Strength Parameters

The following Rock Properties are selected for the slope stability analysis:

\[ \gamma = 24 \text{ kN/m}^3 \]
\[ c = 500 \text{ kN/m}^3 \]
\[ \phi = 34^\circ \]

5.3 Bedding Planes and Joints between Rock Formations

Sheared, weak bedding planes exist between rock formations.

The following parameters based on test data presented in the GDR [1] and GBR [4] are used for modelling the planes.

<table>

</tbody>
</table>

Table 2: Geotechnical Parameters for Bedding Planes and Joints.

During excavation of the canal, wedges may slide into the canal where joints and bedding planes act as sliding planes. The resisting forces on the sliding planes are calculated using friction angle and cohesion of the bedding planes. Full separation of the joints will not be considered. Assuming \( A_{\text{real}} \) as the total area of the slide plane at the face and \( A_{\text{projected}} \) as the real joint plane area which takes into account the persistency of joints, the degree of separation \( k \) of the sliding wedge is described by:

\[ k = A_{\text{real}} / A_{\text{projected}} \]
Hence the resisting forces of a possible sliding wedge can be analysed using:

$$\kappa \times \text{strength}_{\text{joint}} + (1 - \kappa) \times \text{strength}_{\text{rock}}$$

As a conservative approach $\kappa = 0.7$ is selected (i.e. a persistency of 70% has been assumed for the subsequent calculations). This results in an equivalent joint strength of:

$c = 150 \text{ kN/m}^2$

$\phi = 31.5^\circ$

6 GROUNDWATER

Three major groundwater flow regimes are encountered in the rock formations of the project area. The uppermost occurs in the Guelph, Lockport and De Cew formations. This aquifer is connected to the surface water and shows the highest permeability of the entire sequence of geological formations.

7 EXCAVATION METHOD AND SUPPORT MEASURES

Smooth blasting techniques will be employed to excavate the sides of the outlet canal. Any exposed shaly rocks (e.g. the Rochester Formation) or shale layers which are susceptible to deterioration upon exposure to wetting and drying cycles and large temperature differences will be protected by sealing shotcrete.

The vertical walls to be constructed in the rock units generally will not be supported.

The overburden soils will have a slope inclination of 1:2.

A grouting curtain behind the excavation walls is installed prior to excavation in order to avoid excessive water inflow during construction.

The analysis of slope stability is carried out without modelling any rock support measures.

8 CALCULATION MODEL

The calculations are carried out using the EDP program LARIX-4S.
8.1 Slope stability analysis according BISHOP/KREY

The used method by Krey is an iteration method, in the course of which the slip circles are varied until the smallest safety is determined. Starting from an inclination of the slip lines to the horizontal of $45 + \varphi / 2$, a tangential gradient will be considered in the calculation.

8.2 Slope stability analysis according JANBU

The occurrence of discrete slip surfaces are analyzed using the method according to Janbu. This slip surfaces are determined by the horizontal bedding planes and joints that are almost perpendicular to the bedding plane. For the calculation model, the analytical solution for the sliding of a rigid body on an inclined surface is taken as a basis.

The thickness of ground layers, the distance between the joint planes and the lengths of the slip surfaces are presently not known. The calculations are carried out for the worst case when the slip surface cuts through the base of the slope and start developing behind the grout curtain.

8.3 Load assumptions

Dead loads of structural and non-structural elements are based on unit weight and computed volume of the materials.

Live load is assumed to consist of a mobile crane of total weight of 25 tons loaded on a plane of approx. 2 x 3 m. In the calculations the crane load is modelled as a uniform distributed load of approx. 42 kN/m$^2$ (placed 2 m from the existing berm).

The Water table is assumed to be at el 178.2 m (based on NF – 42). Due to the grout curtain installed around the outlet canal a lowest ground water elevation of 174.0 m is considered.

The analysis is performed without water pressure inside the Outlet Canal (dewatered).

8.4 Safety Factors

Ultimate Limit State is considered for the Slope Stability Analyses. Due to uncertainties with respect to appropriate strength parameters a conservative approach for the partial safety factors is chosen.

- Active Load factors $\alpha$ for
  - Dead loads $\alpha_a = 1.1$
  - Live loads $\alpha_f = 1.5$
Resistance factor $\gamma$:
- $\gamma_{\text{cohesion}} = 1.6$
- $\gamma_{\text{friction}} = 1.25$

A model factor $\gamma_{\text{mod}}$ is introduced in addition:

$\gamma_{\text{mod}} = 1.1$ and therefore $R. / S. \geq 1.1$ has to be fulfilled.

ANALYSIS RESULTS

The following calculations were performed for the slope stability of the overburden material.

<table>

Table 4: Results of Slope Stability Analysis for the Vertical Rock Wall.
CONCLUSIONS

The analysis proves, that the stability of excavations is guaranteed without installation of support measures, when the proposed geotechnical parameters are applied.

It is recommended to use slope inclinations of maximum 1:2 within the overburden material.

Adopting conservative calculation parameters it can be concluded, that the vertical walls within the rock units are stable. Care has to be taken to ensure, that the rock beyond the excavation limits is not damaged or destabilized by blasting. Any damaged rock has to be removed to ensure stability of the excavation.

INTRODUCTION

This report provides a preliminary stability analysis for the proposed Intake and Outlet Structure of the Niagara Tunnel Facility Project.

2.3 Codes and Standards

[e] German Standard DIN 1045-1

3 OUTLET STRUCTURE

The outlet structure is a rectangular shaft building between the end of the diversion tunnel and the outlet canal. The outlet structure is 26 m long, 19.3 m wide and approx. 32 m high. The walls on the tunnel side and on channel side has square openings with dimensions of approx. 6.4 m clearance width and height for water flow.

The outlet structure is built of reinforced concrete. The thickness of the floor is 3 m, the thickness of the walls ranges between 2 m at the channel side, 3.9 m at the tunnel side and 3.26 m at the sidewall. To prevent loadings caused by underground pressure from the structure during structure design lifetime a
flexible layer with a thickness of 10 cm is arranged at the sidewalls between the structure’s backside and the excavated face of the ground.

Behind the outlet structure the diversion tunnel cross section changes from a square cross section to a circular cross section within a length of 20 m. This transition zone is an individual structure with changing cross section and changing dimensions of its wall thickness. It will be preliminary analysed within this document.

4 INTAKE STRUCTURE

The intake structure is a similar building as the outlet structure. The dimensions of the structure are:

- Length: 8 m
- Width: approx. 19 m
- Height: approx. 36 m
- Thickness wall Channel side: 2.50 m
- Thickness wall Tunnel side: 2.03 m
- Thickness Sidewalls: 1.49 m

5 GEOLOGY

Twelve stratigraphic formations are identified in the project area. They consist of sequences of sedimentary rock of Ordovician to Devonian age. These are namely the Guelph, Lockport, De Cew, Rochester, Irondequoit, Reynales, Neahga, Grimsby, Power Glen, Whirlpool and Queenston formations. Some of these formations are only a few meters thick.

The intake structure is mainly located in the Lockport formations, while the outlet structure is laying in the Rochester and the Lockport formation. The lithological spectrum of the encountered formation covers limestone, dolostone, sandstone and shale (see chapter 3 of [5] for details).
6 GEOTECHNICAL INPUT PARAMETERS

The input parameters used in the analysis are in accordance with the evaluated calculation parameters included in the "Structural Design Analysis for the Diversion Tunnel" [6].

7 GROUNDWATER

Because of the neighbourhood of the regarded structures to the Niagara River and other water bearing structures the groundwater level close to the structure is assumed at the underground surface level (on the safe side).

8 EXECUTION MEASURES

The pits for the outlet and intake structure are excavated by drilling and blasting. The rock mass is assumed as stable enough, that generally no support of the excavated surface is necessary. In individual cases a shotcrete sealing of the excavation surface against weathering might be appropriate.

The structures are concreted in different steps. Details are given in the corresponding outline specification [7]. The walls will be concreted in adequate segments. The segments are designed in that way, that generally no additional design loads has to be considered on the structure, caused by the construction procedure.

9 CALCULATION MODEL

9.1 Design Loads

9.1.1 Structural and Dead Loads

Dead load (D) of structural and non-structural elements is based on unit weight and computed volume of the materials. The following unit weights are used:

Reinforced Concrete  25.0 kN/m³

Rock / Soil  see [6]
9.1.2 Hydrostatic Pressure

Hydrostatic pressure is considered as a life load (L). It has to be distinguished between the internal hydrostatic pressure and the external ground water pressure.

The applicable "internal water pressure" and "external water pressure" are shown in the geotechnical longitudinal section (2) and will be treated as basis for subsequent analysis.

9.1.3 Seismic Loads

Underground structures are generally less sensitive to seismic effects than surface structures, therefore no seismic loads are considered for preliminary design. At detail design stage a seismic analysis based on actual data will be carried out.

9.1.4 Underground pressures

The structures will be protected against any kind underground pressures by a flexible layer, arranged between the structure's backside and the excavation surface. Details about the layer are given in the corresponding outline specification [6].

9.1.5 Load Combinations

For load combinations not including earthquake, factored loads are determined in accordance with CSA A23.3–94 [a]. Herein the effect due to specified loads is multiplied by a load factor $\alpha$. A load combination factor $\psi$ and an importance factor $\gamma$ is also considered:

$$\alpha_D D + \gamma \psi (\alpha_L L + \alpha_T T)$$

where:

- Load factors $\alpha$ for:
  - Dead loads: $\alpha_D = 1.0$; (0.85 if dead load resists uplift)
9.2 Outlet Structure Design

Structural data

Length: 26 m
Width: 19.3 m
Height: 32 m

Thickness wall Channel side: 2.00 m
Thickness wall Tunnel side: 3.9 m
Thickness Sidewalls: 3.26 m
Thickness Floor: 3.00 m

For the preliminary design of all structural elements it is assumed that the gates are closed and the tunnel is pumped out for maintenance. Therefore the uplift and water pressure, caused by the outside water level and the weight of the structure are active.

9.2.1 Uplift

For design 85 % of the structure weight (dead load) has to be equal the maximum possible water pressure beneath the structure floor.

Maximum possible uplift force:
A = 32 x 26 x 19.3 [m] x 10.0 kN/m³ = 160,576 kN

Structure Weight.
D = (26x19.3x3 [m³] + 2x(26x29x3.26 [m³]) + 12.8x29x(2.0+3.9) [m³] - 6.39(3.9+2.0) [m³] x 25.0 kN/m³ = 209,266 kN
0.85 x D = 177,876 kN > 160,576 kN = A ✓
9.2.2 Preliminary Design of Bottom Plate

Loads:

\[
\begin{align*}
D &= 3 \text{ m} \times 25.0 \text{ kN/m}^3 = 75 \text{ kPa} \\
W &= 32 \times 10 \text{ kN/m}^3 = 320 \text{ kPa}
\end{align*}
\]

Combination:

\[
C = 1.0 \times 1.0 \times (1.25 \times 320 - 1.0 \times 75) = 325 \text{ kPa}
\]

Assumption: plate, flexible supported on four sides; \( L_x / L_y = 26 / 19.3 \approx 1.3 \)

Bending Moment (max.) \( M = 325 \times 26^2 / 30.9 = 7,110 \text{ kNm/m} \)

Design (acc. to DIN 1045-1), Concrete strength = 35 MPa:

\[
k_d = 300 / 7,110^{\frac{1}{3}} = 3.55; \text{ req. } a_s = 2.27 \times 7,110 / 300 \approx 54 \text{ cm}^2 / \text{m}
\]

Minimum required reinforcement (acc. to CSA 23.3-94):

\[
\text{req. } a_s = 0.2 \times 35^{\frac{1}{3}} / 500 \times 300 \times 100 \approx 46 \text{ cm}^2 / \text{m} \quad \text{< 54 cm}^2 / \text{m}
\]

9.2.3 Preliminary Design of Side Walls

Loads:

\[
W = 32 \times 10 \text{ kN/m}^3 = 320 \text{ kPa}
\]

Combination:

\[
C = 1.0 \times 1.0 \times 1.25 \times 320 \text{ kPa} = 400 \text{ kPa}
\]

Assumption: plate, flexible supported on four sides; \( L_x / L_y = 29 / 25 \approx 1.2 \)

Bending Moment (max.) \( M = 400 \times 29^2 / 29.1 = 11,560 \text{ kNm/m} \)

Corresponding Normal Force (pressure):

\[
N = -3.26 \text{ m} \times 29 \text{ m} \times 25.0 \text{ kN/m}^3 = -2,364 \text{ kN/m}
\]

Design (acc. to DIN 1045-1), Concrete strength = 35 MPa:

\[
M_{des} = 11,560 + 2,364 \times 1.58 = 15,295; k_d = 326 / 15,295^{\frac{1}{3}} = 2.63;
\]

\[
\text{req. } a_s = 2.32 \times 15,295 / 326 - 2,364 / 45 \approx 56 \text{ cm}^2 / \text{m}
\]

Minimum required reinforcement (acc. to CSA 23.3-94):

\[
\text{req. } a_s = 0.2 \times 35^{\frac{1}{3}} / 500 \times 326 \times 100 \approx 77 \text{ cm}^2 / \text{m} \quad \text{> 56 cm}^2 / \text{m}
\]

9.2.4 Preliminary Design of Channel Side Wall

The load bearing is assumed in the wide side direction. The edges of the wall are assumed to be rigid connected to the sidewalls.

Loads:

\[
W = 12.5 \times 10 \text{ kN/m}^3 = 125 \text{ kPa}
\]
Combination: \[ C = 1.0 \times 1.0 \times 1.25 \times 125 \text{ kPa} = 156 \text{ kPa} \]

Bending Moment (Edge): \[ M = 156 \times 16^2 / 12 = 3,328 \text{ kNm} / \text{m} \]
(Field): \[ M = 156 \times 16^2 / 24 = 1,664 \text{ kNm} / \text{m} \]

Design (acc. to DIN 1045-1), Concrete strength = 35 MPa:

\[ k_d = 200 / 3,328^{1/3} = 3.46; \text{ req. } a_s = 2.27 \times 3,328 / 200 \approx 38 \text{ cm}^2 / \text{m} \]

Minimum required reinforcement (acc. to CSA 23.3.-94):

\[ \text{req. } a_s = 0.2 \times 35^{1/3} / 500 \times 200 \times 100 \approx 47 \text{ cm}^2 / \text{m} \]
\[ \text{m} > 38 \text{ cm}^2 / \text{m} \]

9.2.5 Preliminary Design of Tunnel Side Wall

The loads on the tunnel side wall are lower than on the above mentioned sidewalls, but the wall is thicker than these. Therefore it is assumed, that the minimum reinforcement are valid for design.

Minimum required reinforcement (acc. to CSA 23.3.-94):

\[ \text{req. } a_s = 0.2 \times 35^{1/3} / 500 \times 390 \times 100 \approx 92 \text{ cm}^2 / \text{m} \]

9.3 Intake Structure Design

Structural data

- Length: 8 m
- Width: 18.9 m
- Height: 36 m

Thickness wall Channel side: 2.50 m
Thickness wall Tunnel side: 2.03 m
Thickness Sidewalls: 3.00 m
Thickness Floor 3.00 m

For the preliminary design of all structural elements it is assumed that the gates are closed and the tunnel is pumped out for maintenance. Therefore the uplift and water pressure, caused by the outside water level and the weight of the structure are active.
9.3.1 Uplift

For design 85% of the structure weight (dead load) has to be equal the maximum possible water pressure beneath the structure floor.

Maximum possible uplift force:
\[ A = 36 \times 8 \times 18.9 \text{[m]} \times 10.0 \text{kN/m}^3 = 54,432 \text{kPa} \]

Structure Weight.
\[ D = (8 \times 18.9 \times 3.0 \text{[m]}^3) + 2 \times (8 \times 33 \times 3.0 \text{[m]}^3) + 12.9 \times 33 \times (2.5 + 2.03) \text{[m]}^3 - 6.39^2 (2.5 + 2.03) \text{[m]}^3) \times 25.0 \text{kN/m}^3 = 94,526 \text{kPa} \]

\[ 0.85 \times D = 80,347 \text{kPa} > 54,432 \text{kPa} = A \]

9.3.2 Preliminary Design of Bottom Plate

Loads:
\[ D = 3 \text{m} \times 25.0 \text{kN/m}^3 = 75 \text{kPa} \]
\[ W = 36 \times 10 \text{kN/m}^3 = 360 \text{kPa} \]

Combination:
\[ C = 1.0 \times 1.0 \times (1.25 \times 360 - 1.0 \times 75) = 375 \text{kPa} \]

Assumption: plate, flexible supported on four sides; \( L_x / L_y = 15.9 / 8 \approx 2.0 \)

Bending Moment (max.) \( M = 375 \times 15.9^2 / 40.3 = 2,352 \text{kNm} / \text{m} \)

Design (acc. to DIN 1045-1), Concrete strength = 35 MPa:
\[ k_d = 300 / 2,352^{0.6} = 6.18; \text{req.} a_s = 2.22 \times 2,352 / 300 \approx 17 \text{cm}^2 / \text{m} \]

Minimum required reinforcement (acc. to CSA 23.3.-94):
\[ \text{req.} a_s = 0.2 \times 35^{0.6} / 500 \times 300 \times 100 \approx 46 \text{cm}^2 / \text{m} > 17 \text{cm}^2 / \text{m} \]

9.3.3 Preliminary Design of Side Walls

Loads:
\[ W = 33 \times 10 \text{kN/m}^3 = 330 \text{kPa} \]

Combination:
\[ C = 1.0 \times 1.0 \times 1.25 \times 330 \text{kPa} = 413 \text{kPa} \]

Assumption: plate, flexible supported on four sides; \( L_x / L_y = 33 / 8 \approx 4.1 \)

Bending Moment (max.) \( M = 413 \times 33^2 / 40.3 = 11,160 \text{kNm} / \text{m} \)

Corresponding Normal Force (pressure):
\[ N = -3.00 \times 33 \times 25.0 \text{kN/m}^3 = -2,475 \text{kN} / \text{m} \]
Design (acc. to DIN 1045–1), Concrete strength = 35 MPa:

\[ M_{\text{des}} = 11,160 + 2,475 \times 1.40 = 14,625; \ k_d = 300 / 14625^{1/3} = 2.48; \]
\[ \text{req. } a_s = 2.29 \times 14,625 / 300 - 2,475 / 45 \approx 57 \text{ cm}^2 / \text{m} \]

Minimum required reinforcement (acc. to CSA 23.3.–94):

\[ \text{req. } a_s = 0.2 \times 35^{1/3} / 500 \times 300 \times 100 \approx 71 \text{ cm}^2 / \text{m} > 57 \text{ cm}^2 / \text{m} \]

9.3.4 Preliminary Design of Channel Side Wall

The load bearing conditions are assumed to be similar than at the outlet structure. Therefore it is assumed, for the preliminary design that the minimum required reinforcement is valid for design.

Minimum required reinforcement (acc. to CSA 23.3.–94):

\[ \text{req. } a_s = 0.2 \times 35^{1/3} / 500 \times 250 \times 100 \approx 59 \text{ cm}^2 / \text{m} \]

9.3.5 Preliminary Design of Tunnel Side Wall

The load bearing conditions and the dimensions are similar to the Channel side wall. Therefore it is assumed, for the preliminary design that the minimum required reinforcement is valid for design.

Minimum required reinforcement (acc. to CSA 23.3.–94):

\[ \text{req. } a_s = 0.2 \times 35^{1/3} / 500 \times 203 \times 100 \approx 48 \text{ cm}^2 / \text{m} \]

9.4 Diversion Tunnel, Transition Area

As described above, the cross section within the Diversion Tunnel transition area changes from a square cross section to a circular cross section. Therefore the structure's contour changes from a frame to a ring.

For preliminary analysis the most unfavourable conditions are regarded. This is a frame contour at the entrance.

Similar to the intake and outlet structure the structure of the transition area is covered with a flexible material layer all around, to prevent stresses, caused by any kind of underground reactions. Therefore only the structural dead weight and the suitable water pressure are valid for the preliminary design. The
dimensions are given in the corresponding drawing (4), (6). With respect to this conditions, the structure is loaded as shown below:

Bending moments

The required reinforcement are calculated as listed below.

1 INTRODUCTION

This report provides a preliminary stability analysis for the pipes, culverts and minor items of the Niagara Tunnel Facility Project. In detail this will be

- The water collection sump at the top of the shafts of the dewatering system
- The collection pipe with an inside diameter of 1,000 mm
- The culvert at the outlet of the collection pipe

2 REFERENCES

2.1 Documents

2.2 Drawings

(1) STRABAG/ILF (2005): Niagara Tunnel Facility Project - Diversion Tunnel, Plan and Longitudinal Section (PD-01-1001, PA-01-1001)
2.3 Codes and Standards

[d] German Standard DIN 1045–1

3 WATER COLLECTION SUMP

The water collection sump has a circular contour with a inside diameter of 3.05 m and is 3.75 m deep. It is made of concrete. Its wall is designed with a thickness of 45 cm. The water collection sump is installed in a pit and backfilled with granular filling material.

For design the parameters of the backfill material are assumed with $\gamma = 22$ kN/m$^3$ (specific weight) and $\phi = 30^\circ$ (angle of friction). With that the earth pressure is given to approx. 20 kN / m$^2$. Considering a compaction pressure during backfill with 40 kPa, the pressure within the concrete will be about 176 kPa. Therefore the wall thickness is enough. Reinforcement is required for constructional tasks only.

4 COLLECTION PIPE

The collection pipe will have a inside diameter of 1,000 mm and will be approximately 227 m long. It will be laid in a ditch with a maximum depth of 4.0
m. The pipe will be embedded in a 20 cm thick sand layer and backfilled. With the above mentioned assumptions the overburden weight pressure will be approximately 80 kPa and the force within the ring will be 40 kN / m.

5 DEWATERING OUTFALL

The dewatering outfall structure is installed at the end of the above mentioned collection pipe where the water is flowing in a concrete lined open ditch and from that to the Ontario Hydro Channel. The outfall structure consists of a concrete wing wall against the ground with foundation. The wall is approximately 10 m long and 3.3 m high. The wall thickness is 60 cm at the bottom and 45 cm at the crown. The foundation is limited to the centre of the structure, arranged in front and beneath of the wall, with a length of 3.3 m, a width of 3.45 m and a thickness of 90 cm. Reference is made to (3)

The underground will be regarded with $\gamma = 22 \text{ kN/m}^3$ (specific weight) and $\varphi = 30^\circ$ (angle of friction). Considering this, the earth pressure will be approx. 23 kPa.

Regarding sliding of the construction, the active force (caused by earth pressure) shall be less than the ground resistance force in the joint beneath the foundation. This ground resistance force is caused by the dead weight of the construction.

Regarding only the weight of the foundation this will be $3.3 \times 3.45 \times 0.90 \text{[m}^3\text{]} \times 25 \text{ kN/m}^3 = 256 \text{ kN}$. The ground resistance force will be $256 \text{ kN} \times \tan 30^\circ = 148 \text{ kN}$

With respect to the construction the maximum earth pressure force is 130 kN

Therefore the safety against sliding is given to 1.14 under this assumptions, laying on the conservative side. Detailed analysis and the adequate validation of the underground behaviour is required while construction.

For the concrete structure design a Concrete with a strength of 35 MPa is assumed. With that the static required reinforcement will be approximately 8 cm$^2$ / m at the foundation / wall section and at the beginning of the wing walls. The minimum required reinforcement is given to 10 cm$^2$ / m.

3.0 DESIGN ANALYSIS .......................................................................................................... 4

3.1 CODES, STANDARDS AND SPECIFICATIONS .......................................................... 4

3.2 DESIGN METHODS AND PROCEDURES ................................................................. 4
1.0 SCOPE

The civil works included in this plan are primarily site facilities comprising:

1. Roads and Parking;
2. Fencing, Gates and Barriers; and
3. Stockpiles, disposal and water treatment facilities.

2.0 PRELIMINARY DESIGN

2.1 Preliminary Design Drawings

Preliminary design drawings, Nos. MH-6008 and MH-6009, were prepared to illustrate the result of the design, which will be finalized at the detailed design stage. The drawings are included in Chapter 6 of the Technical Proposal.

2.2 References and Design Methods

The preliminary design was conducted in accordance with document MH-3002: “Design Basis and Method Statements for Design and Construction Facilities at the Intake and Outlet Areas” prepared for this project and included in previous chapters.

The Contractor and the Specialist Subcontractors of the group have been and will continue to be contacted throughout the entire design and contract preparation process to provide valuable construction input to ensure that the design is useful, constructable and economical, without compromising the quality of the final work.

2.2.1 Temporary Facilities

- Intake Temporary Facilities:

  At the intake a construction laydown area will be placed to the south of Niagara Parkway. This facility will be used in conjunction with all associated works at the intake. This site will be approximately 182 m x 76 m. It will be fenced and a lockable gate provided for security. Their surface will be graded stone and maintained throughout the project life. The facing side to Niagara Parkway of the lay down area shall also have a screen wall erected to downplay the activity within the compound and the public activity along the parkway. For additional reference, refer to Drawing No. MH-6008-00.

- Outlet Temporary Facilities:

  At the outlet the construction offices will be located adjacent north south portion of the temporary access road. This area is fully fenced and will be approximately 400 m x 50 m. This site will be fully serviced by temporary utilities from Stanley Avenue. In addition Material Yards will be placed throughout the site and will be fully accessible and within the fenced construction area. Their surface will be graded stone and maintained throughout the project life. For additional reference, refer to Drawing No. MH-6009-00.
2.2.2 Roadways

- **Intake Roadways:**

  At the intake site a temporary roadway is being constructed to allow access to the site from Portage Road to the construction laydown area and across Niagara Parkway to the construction area at the intake. This will eliminate any need for construction traffic to utilize Niagara Parkway. Roadside ditches will be provided to carry any surface water generated from the roadway into the existing and natural drainage system. A temporary traffic signal will be installed at the intersection of the Access Road and Niagara Parkway to alleviate conflict with construction traffic crossing Niagara Parkway. For additional reference, refer to Drawing No. MH-6008-00.

  The existing recreation trail will be relocated to a new location as shown on the drawing to minimize interference of visitors to the area and the construction.

- **Outlet Roadways:**

  At the outlet site a new permanent paved access road is being constructed from Stanley Avenue to provide access to the work zones. However only a 180 m section of this road will be built, and beyond this section a temporary roadway is being constructed to provide access to the material stockpiling area and the outlet location. These roadways will be in place until the end of the project and then removed and the area restored to original conditions. Roadside ditches will be provided along these roadways to carry surface drainage from the roadway and other site locations to a detention/settling basin for eventual discharge into the canal system. For additional reference, refer to Drawing No. MH-6009-00.

  All roadway design, horizontal and vertical alignments, road widths, surface details, drainage, intersection details, and the like, will comply with highway design requirement appropriate to the class of the road as provided in the above-quoted references.

2.2.3 Fencing

Fencing providing boundary separation and security to the sites will be primarily chain link fences. This will help to eliminate any potential interference between the public and the construction activities. At the intake area, some of the work zones will be fenced off using full height hoardings to afford even better separation and minimize the impact on the appearance of this tourist area.

For additional reference and specific locations, refer to Drawing Nos. MH-6008 and MH 6009.

2.2.4 Stockpiles

During the excavation of the tunnel a large quantity of material primarily rock will be stockpiled between the two power canals as shown on MH-6009. These stockpiles will be between approximately 5 m to 6 m in height with proper and safe side slopes and with the top surface level and graded.
The stockpiles shall be piled in lifts of not more than 300 mm. The stockpile will be setback at a minimum 20 m from the canals and a perimeter trench will be implemented to gather any surface runoff from the stockpiles, collected in a settling basin and discharged through filter cloth into the canal. The ditch surface shall be protected by seeding, and strawbale flow-checks will be provided at 250 m intervals, and before every culvert and intersecting ditch. When the grade of the ditch is steeper than 10%, rockfill check dam will be installed. No stockpile is within 5 m from any part of the tower structures or the location in plan of the overhead transmission lines. A temporary construction pad will be provided for holding materials suspect of contamination. The runoff will be suitably treated prior to discharge. Excavated materials suitable for aggregate production or other uses will be stockpiled separately.

As stated previously, the specifications for stockpiles are located in the Draft Design/Build Agreement and Concept Drawings and also in OPG’s “Management of Excavated Material” document dated December 2004 and OPG’s “Management Plan for BTEX” dated December 2004. If the specifications in the Draft Design/Build Agreement and Concept Drawings prevail, then the following will be implemented. A temporary stockpile will be located between the canals and a runoff pond provide for runoff from the excavated materials. This will be used for specific contaminated materials from the tunnel excavation. The runoff will be pumped to the water treatment facility prior to final discharge. The runoff pond and the temporary stockpile will be lined with synthetic material or a minimum of an impervious material to eliminate ground contamination.

If the design is to meet the requirements in OPG’s “Management of Excavated Material” and “Management Plan for BTEX”, then certain rock formations have specific temporary and/or permanent storage requirements based on the information provided by the Reuse of Excavated Materials Committee. The limestones/dolomites above the Rochester Shale formation are to be segregated and stockpiled separately for reuse by the Project. The shales potentially containing BTEX (Rochester, Grimsby and Power Glen formations) are to be isolated permanently in the main disposal area with a perimeter drain leading to the retention pond. The Queenston Shale may be used by the clay/brick industry at a later date and therefore should be stored in the main disposal area separate from the other rock for easy access when required. All other rock types are to be placed in the main disposal area for permanent disposal separately from the other in this area.

The storage area for the excavated material potentially contaminated with BTEX will be approximately 400 m long by 100 m wide and will either have a compacted clay base or impermeable geotextile lining. Within this area, there will be a 10 m wide buffer area around the perimeter which will contain the drainage ditch/outside berm. The shale will be stockpiled in lifts less than 300 mm and the slope will be no greater than two horizontal to one vertical (2:1). The run-off will be directed towards the retention pond for treatment, if required.

**3.2.5 Disposal**

The disposal will be conducted in compliance with the Owner’s Mandatory Requirements, section 3.
As stated above, the specifications for stockpiles are located in the Draft Design/Build Agreement and Concept Drawings and also in OPG’s “Management of Excavated Material” dated December 2004 and OPG’s “Management Plan for BTEX” dated December 2004. On-site permanent disposal of excavated material is required for rock from the Rochester, Grimsby and Power Glen formations and rock other than Queenston formation and limestones/dolomites. The Queenston shale will be temporarily stored at the main disposal area and the limestones/dolomites will be reused. The section of the permanent disposal area storing the Rochester, Grimsby and Power Glen formations will be either lined with clay or geotextile to reduce potential soil and groundwater contamination. Runoff will be collected and discharged to the retention pond for sampling and treatment, if required, for final discharge.

Any excavated materials suitable for aggregate production will be stockpiled separately and used where applicable. Any surplus will be removed from the site at the end of the contract. No excavated material or discharge of water prior to treatment will be spilled or placed into any watercourse at the site.

3.0 DESIGN ANALYSIS

3.1 CODES, STANDARDS AND SPECIFICATIONS
The facilities will be designed in compliance with the codes, standards and specifications listed in Section 6 above.

3.2 DESIGN METHODS AND PROCEDURES
The civil works will be designed by using recognized methods and procedures, which include the established and industry standard software in performing in the installation of all work.

1.0 SCOPE

This document provides information regarding the Strabag group’s preliminary design layout and arrangements for the cofferdams and the temporary dock, both are to be used at the intake area.

The information was supplied by specialist contractors as described below.

2.0 COFFERDAM

Preliminary Design Drawings and Method Statement were designed by Bermingham Foundations in conjunction with Isherwood Geostructural Engineers, attached in the appendix of this document.

3.0 TEMPORARY DOCK

Layout of the Barge Unloading Dock at the Intake area as part of the approach wall system prepared by McNally Construction Inc. is also enclosed in the appendix of this document.

As discussed in document MH-3001, the additional loading imposed by the extraordinary construction loading on the approach wall at this location has been adequately accounted for.

   4.2 WATERLINE RELOCATION............................................................................................... 2
5.0  CONSTRUCTION TECHNIQUES AND EQUIPMENT ...................................................... 3
1.0 GENERAL

The document will describe preliminary design issues relating to:

1. Demolition and Disposal of Dewatering Structure at the PGS; and
2. Relocation of the Waterline as a result of item 1.

2.0 PRELIMINARY DESIGN PROCESS

The design will make reference to document no. MH-3002: “Design Basis and Method Statements for Temporary Construction Facilities at the Intake and Outlet Areas” included in Chapter 3 of this proposal. Due to nature of the work, and a number of available options for the work to be determined during the detailed design and construction, no drawing is considered required to illustrate the work at this stage.

Input from the Contractor and the Specialist Subcontractors have been and will continue to be sought to supplement the design to ensure that the solution selected will address all issues and will be efficient, constructable and economical.

Due to the many impacts of these works on the operation of the PGS, as well as areas where the waterline is supplying, the input from related staff of OPG will also be sought as the design proceeds.

3.0 CODES AND STANDARDS

The design of these 2 components will be mainly based on the Owner’s Mandatory Requirements and Questions and Answers issued related to the work. Other references will include:

1. OPSS (Ontario Provincial Standard Specifications)
2. CSA Standard Z107.0-00 (Standard for Certification of Noise Barriers February 2000)
3. CAN/CSA-S6-00 (Canadian Highway Bridge Code)
4. Other CAN standards, see applicable specifications included
5. Other CSA Standards, see applicable specifications included
6. Niagara Tunnel Facility Project - Invitation to submit Design/Build Proposals, Ontario Power Generation (Amendment 1, February 2005)
7. Ontario Provincial Standard Drawings (OPSD)
4.0 PRELIMINARY DESIGN DESCRIPTION

4.1 Demolition of the Dewatering Structure

The existing dewatering structure at the PGS Canal is a 45 m long, 6 span reinforced concrete structure, with a 6.7 m wide walking surface on the top. The 5 piers in the water are tall concrete piers with a wide base but tapering up towards the top but all are up to 17 m in height and are sitting on the rock surface of the bottom of the canal, including some embedment into the rock stratum. It is not known whether the structure is manufactured from precast units, but from the information provided, there is definitely a possibility of this and as such it may help to remove the component in convenient chunks instead of breaking into small debris using a concrete breaker.

The 6 span openings are actually gate openings used to close the canal from the main HEP canal for dewatering purposes, though according to information provided to the Proponent, the structure has not been used. OPG provided additional information on the condition of the structure through inspection reports, and suggested that there are damages to certain parts of the structure especially at the abutments and one of the piers (pier 1), and does not use the structure for vehicular traffic anymore.

The method of demolition will be such as to minimize impact on the operation of the PGS and coordination with the timing and duration, as well as the proposed method of removal, will be discussed with OPG and agreed prior to implementation. Sufficient advance notification will be provided to ensure all preparative work be made and all affected personnel informed of the impending work.

The entire superstructure will be removed and the remaining abutment and exposed rock surface stabilized where necessary and where confirmed by the engineer. The pier will be removed up except the last 300 mm which should be intact and firmly fixed into the rock.

It is expected that the deck will be sawcut or flame cut into large pieces that could be handled by a crane seated on the bank with sufficient reach and capacity. The piers and the abutment units designated for removal will then be cut out and removed in pieces. Some underwater work will be required to remove submerged portions of the piers up to 300mm above the canal bed. All loose abutment and rock slopes exposed will be stabilized using bolts, anchors or other appropriate techniques.

Debris catching device will be implemented together with use of barges, at the endorsement of OPG, to minimize concrete debris falling into the water. All sawcutting operations will be controlled and effluent removed using vacuum machine. Large cut reinforced concrete chunk will be removed by lifting from the banks and carting away in truck to designated disposal areas.

4.2 Waterline Relocation

During construction an existing waterline (apparently 8” diameter, as shown on the as-built drawings) will be relocated from the existing PGS dewatering structure prior to the demolition of the structure. The relocation can either be a surface laid/ buried waterline laid along the banks of
the PGS Canal, and cross the canal at the roadway located outside the PGS station, or on a new utility bridge over the canal at its existing location. Both alternatives will be evaluated, considering cost, timing, impact to other work, etc., and discussed with OPG staff prior to selecting the suitable approach.

The relocated waterline will be constructed to the same standards and details as the existing waterline.

4.3 Disposal

The disposal will be conducted in compliance with the Owner’s Mandatory Requirements, section 3.

Concrete debris will not be subject to be reused, and will be removed off site to designated disposal areas.

5.0 CONSTRUCTION TECHNIQUES AND EQUIPMENT

The work will be completed primarily utilizing standard construction methods. The equipment used for the demolition of the PGS dewatering structure include the use of sawcutting or flame cutting equipment, barges, lifting equipment and debris collecting setup. When necessary, underwater work may be required to retrieve concrete components submerged in the water at the bottom of the canal.

1.0 INTRODUCTION

1.1 GENERAL

The Intake Approach and Accelerating Walls, which form part of the Niagara Tunnel Facility Project, are located upstream of the INCW Structure. The layout, alignment, geometric dimensions, and top elevations of these walls follow the concept plan defined by OPG.

The purpose of the Intake Approach and Accelerating Walls is to direct a continuous supply of water to the Diversion Tunnel through the Intake Structure. In carrying out this function, specific hydraulic and environmental requirements must be met under all operating conditions.

1.2 SCOPE

This report provides a summary of the key results of structural analysis carried out for the preliminary design of the proposed Intake Approach and Accelerating Walls.

The preliminary design parameters, codes and standards and methods of analysis are presented to illustrate the design process used for developing the design as shown in the drawings contained in the Proposal submission (see Sub-section 2.2 below).

The preliminary structural design of other components of the Niagara Tunnel Project is addressed by other relevant documents elsewhere in the Proposal submission.

2.0 REFERENCES

2.1 DOCUMENTS

The following documents form the basis of the design of the Intake Approach and Accelerating Walls:

1. Ontario Power Generation (2005), Niagara Tunnel Facility Project, Owner’s Mandatory Requirements, part of Invitation to Submit Design/Build Proposals, Appendix 1.1 (pp).
2. Ontario Power Generation (2005), Niagara Tunnel Facility Project, Geotechnical Baseline Report, part of Invitation to Submit Design/Build Proposals, Appendix 5.4.
3. Ontario Power Generation (2005), Niagara Tunnel Facility Project, Concept Drawings, part of Invitation to Submit Design/Build Proposals, Appendix 1.1 (h).

2.2 DRAWINGS

The engineering design of the Intake Approach and Accelerating Walls is shown in the following drawings:
1. Morrison Hershfield (2005), Niagara Tunnel Facility Project, Intake Works – General Notes, document MH-6001

2.3 CODES AND STANDARDS

The requirements of the codes, regulations and guidelines where applicable as follows:

3. CSA Standard CAN3-A23.3-94: Design of Concrete Structures
5. Dam Safety Regulation under the Lakes and Rivers Improvement Act (Proposed Draft), Ministry of Natural Resources (November 2001)
6. Dam Safety Guidelines, Canadian Dam Association (January 1999)
7. Guidelines and Criteria for Approval under the Lakes and Rivers Improvement Act, Ministry of Natural Resources (Draft, May 1997)

The preliminary design was also carried out in accordance with the following standards and specifications:

2. CSA Standard CAN3-A23.1-94: Concrete Materials and Method of Concrete Construction
3. CSA Standard CAN3-A23.2-94: Methods of Test for Concrete

During detailed design, it is expected that the above-named references will continue to be used as bases for design and construction of the proposed work.
3.0 DESIGN DESCRIPTION

3.1 PRECAST CONCRETE MODULAR SYSTEM

The Intake Approach and Accelerating Walls have been developed based on the precast reinforced concrete modular design concept. Each wall is constructed with a series of structurally independent reinforced concrete modules, filled with rock-fill materials and capped with concrete cover slab over the full length of the wall.

The individual wall will be constructed by stacking up either two or three units high as required to form a continuous wall to direct the water flow.

4.0 DESIGN DATA

4.1 DESIGN LOADS – PRELIMINARY DESIGN

At the proposal stage, a preliminary design has been conducted on the structures based on available information and design references as given in this section. The design will obviously need development during the detailed design stage, when investigation and other design data will be made available to the designer.

The structures were designed to withstand all temporary, permanent, construction, environmental, normal, unusual and extreme loads, in all possible combinations.

All structural components were checked to provide adequate capacity to safely sustain the prescribed design loads. The types of loads for which the structures have been designed to withstand, and will continue to be addressed during the detailed design stage, include the following:

4.1.1 Structural and Dead Loads (D)

All permanent masses of the structural components and all permanent construction materials including the permanently located attachments and equipment systems.

The unit weights used for computing the dead loads are:

- Concrete 24.0 kN/m³
- Back-fill 22.0 kN/m³
- Rock-fill 20.0 kN/m³
- Water 10.0 kN/m³

4.1.2 Hydrostatic Pressures

Water surface elevations in the GIP given in Table 1 (based on NAD83 system) have been used to compute hydrostatic pressures on the wall structure. These values will be reviewed and continue to be used in the detailed design stage.
Hydrostatic loads are imposed under the following conditions:

(a) Operating Water Pressures (H)
The external water pressure exerted by water above ground is governed by the specified maximum water levels. When used as stabilizing force acting on the structure in a stability analysis, these forces must be conservatively estimated. See Table 1 for appropriate design water elevations.

(b) Design Flood (F)
The water level under inflow flood scenario varies between the 200-year flood and the Probable Maximum Flood (PMF) as prescribed in the OPG Invitation document. See Table 1 for appropriate design flood elevations.

<table>

<td>PMF</td>
<td>173.17</td>
</tr>
</tbody>
</table>

4.1.3 Soil Pressures (S)

Earth pressures due to soil or rock back-fill will be imposed against the Intake Approach Wall structure.

For preliminary design purpose, a granular back-fill with the following properties is assumed for the design analysis:

- Moist Unit Weight \( 22.0 \text{ kN/m}^3 \)
- Submerged Unit Weight \( 12.0 \text{ kN/m}^3 \)
- Angle of Internal Friction \( \Phi = 35^0 \)
- Cohesion \( C = 0 \)

Since the wall modules are not bonded to the foundation, active pressure is likely to mobilize rather than pressure at “rest”. In such case, Coulomb’s equation may be used for the determination of earth pressure coefficients which are then used for determining pressures and forces acting on the retaining wall.

For preliminary design purpose, a conservative value of \( K_a = 0.4 \) is assumed for analysis.

The pressure and forces below the water table will take into account the submerged unit weight of the same material.
Soil data and any other pertinent parameters used in the design analysis shall be evaluated in consultation with the geotechnical engineer before being adopted for the final design.

4.1.4 Ice Load (I)

The structure has also been designed to withstand the forces generated by ice movement against it. Ice forces may include dynamic loads generated by ice floes striking the structure, and static loads generated by thermal expansion or contraction of the ice and by fluctuations in the water levels.

The magnitude of thermal ice load is governed by a number of controlling factors such as ice thickness, shoreline confinement, water velocity, water level fluctuation, rate of temperature rise, etc. Normally, thermal ice loads range from 37 kN/m to 146 kN/m. For the Niagara site, design ice load of 73 kN/m acting 0.3m below water level is taken for preliminary design purpose.

4.1.5 Seismic Loads (E)

The earthquake loadings used in the design of the structure are based on design earthquakes and associated ground motion parameters determined from seismological evaluation for the specific site. Where site specific study has not been conducted, seismic zone maps of the National Building Code proposed for the 2005 revision are to be used.

Two levels of seismic loads are usually considered for the design: (a) the Maximum Design Earthquake (MDE) having an extremely low probability of annual exceedence, and (b) the Operating Basis Earthquake (OBE) used in conjunction with ice loading and having a probability of annual exceedence of 1 in 200. See Table 2 for recommended design response spectra generated by a probabilistic seismic hazard analysis conducted for the Niagara region.

4.1.6 Construction Loads (C)

Construction lifting loads included dead weights in air or under water plus 50% for impact allowance during handling, lowering, barging, launching and controlled sinking operations of the precast modules.

Construction loads due to a 40 Tonnes crane is also considered at a segment of the wall at a location near the Intake or temporary dock facility, as requested by the Contractor for storage and handling of precast units.

4.2 LOAD COMBINATIONS

During detailed design, all combinations of loads that may act simultaneously during construction, normal plant operation or abnormal environmental conditions shall be considered.

The loading conditions considered in concrete structure designs and overall structural stability analysis shall include but not limited to the following:

1. Loading Case No. 1 – normal loading condition – Construction
   Any combination of loads that may act simultaneously during the construction period, including lifting and handling loads, crane loads for construction activities, etc.

2. Loading Case No. 2 – normal loading condition – Summer Operating
   Any combination of loads that may act simultaneously during normal operation.

3. Loading Case No. 3 – normal loading condition – Ice Load
   Any combination of loads that may act simultaneously due to ice loading effects on the structural components.

4. Loading Case No. 4 – unusual loading condition – IDF\(^1\)
   Any combination of loads that may act simultaneously during a 200-year flood.

5. Loading Case No. 5 - extreme loading condition – PMF\(^2\)
   Any combination of loads that may act simultaneously during this extreme environmental event which has a low probability occurrence.

\(^1\) IDF = Inflow Design Flood
\(^2\) PMF = Probable Maximum Flood
6. Loading Case No. 6 – extreme loading condition – MDE\(^3\)
   The Intake Approach and Accelerating Walls, being a conventional structure (i.e. not dam safety related), shall be designed to satisfy the requirements stipulated in the National Building Code of Canada.

5.0 STABILITY ANALYSIS

5.1 GRAVITY METHOD OF ANALYSIS

Stability of the wall structures has been verified by limit equilibrium method using un-factored loads. The computed factors of safety against sliding, and resulting stresses along any critical sections within the structure or at the base shall not exceed the minimum acceptable factors of safety and allowable working stresses specified for the normal, unusual and extreme load combinations.

5.1.1 Sliding

Factor of safety against sliding along any horizontal plane has been calculated based on the following:

- Factor of Safety (Sliding) = \( \mu \sum V / \sum H \)
  where \( \mu \) = coefficient of friction at the plane considered
  \( \sum V \) = total vertical load acting on the plane
  \( \sum H \) = total net horizontal load acting on the plane

5.1.2 Location of Resultant

The factor of safety against overturning acting on the plane under consideration has been computed as follows:

- Factor of Safety (Overturning) = \( \sum M_R / \sum M_O \)

   Alternately, the location of the resultant acting on the plane under consideration shall be calculated as follows:

- Distance from the toe = \( ( \sum M_R - \sum M_O ) / \sum V \)
  Where \( \sum M_R \) = sum of restoring or stabilizing moments about toe
  \( \sum M_O \) = sum of overturning moment about toe
  \( \sum V \) = total vertical load acting on the plane

\(^3\) MDE = Maximum Design Earthquake
5.1.3 Contact Stresses

It is expected that the stresses acting on the foundation under all the loading conditions are likely to be small. Since these walls will be founded on solid rock, the stresses are not critical either for the concrete or the foundation and therefore these are not a design concern.

In the final design stage, a geotechnical investigation based on field inspections and analysis will be carried out to the extent deemed necessary.

5.1.4 Acceptance Criteria

Most critical load cases have been developed and considered in computing the factors of safety against sliding, overturning, etc.

The Owner’s Mandatory Requirements stipulated that the following conservative assumptions:

1. There is no cohesion at the concrete-rock interface.
2. Passive pressure due to back-fill shall not be considered.
3. Rock anchors to provide structural stability shall not be allowed.

The acceptance criteria for sliding stability of concrete gravity structures are given in Table 3.

<table>

<td>Middle 1/2</td>
<td>1.3</td>
</tr>
<tr>
<td>Extreme</td>
<td>Within base</td>
<td>1.0</td>
</tr>
</tbody>
</table>

Note:

Analysis shall be based on zero cohesion across the prospective failure plane as stipulated by OPG.

5.2 SEISMIC ANALYSIS

Unlike earth structures which often are susceptible to liquefaction and large deformation due to slip circle failure, well designed and constructed concrete gravity structures should be able to withstand even very strong earthquake motions. The experience data based on observations of historical earthquake damages demonstrated that indeed concrete gravity structures are generally safe.

This is mainly because explicitly earthquake forces are transient oscillatory in nature. These forces will vary with time and alternate between one direction to opposite direction. Furthermore, the inertia forces are usually not expected to be applied in the same direction for a
sufficiently long period of time to induce significant rotational or sliding displacements that are actually detrimental to the overall structural stability of the gravity structure.

Therefore, it is now well established that traditional static analysis which does not recognize the dynamic response of the structural system prescribed by previous codes and practices is meaningless. As a result, factors of safety against overturning and sliding are no longer required to be computed.

In fact, it has been verified by seismic studies that potential deformations of simple concrete gravity structures induced by earthquake ground motions are most likely to be small even under the most severe seismic event. Hence, it is concluded herein that further seismic analysis is not necessary at this design phase.

5.3 REINFORCED CONCRETE DESIGN

The reinforced concrete hydraulic structures have been designed in accordance with the Strength Design Method, and this shall continue be adopted during detailed design. The structural members will have a required strength to resist design loads and the factored load combinations specified in Sub-Section 4.1 and 4.2.

The load factors as prescribed in CSA A23.3 shall be applied and the total factored design load shall be increased by the hydraulic factor \( H_f = 1.3 \). The hydraulic factor is used to improve crack control for massive hydraulic structures which usually are lightly reinforced.

The hydraulic factor is not applicable for sliding or overturning stability analysis.

5.3.1 Design Strength

The strength of a structure or individual member must exceed the demand (required strength) for all foreseeable loads without failure or significant distress. The nominal strength must be reduced by a resistance factor to account for the variability in the strength. For this purpose, the resistance factors prescribed in CSA A23.3-94 have been applied and shall continue to apply during detailed design.

6.0 DESIGN ANALYSIS RESULTS

In the design of the Intake Approach and Accelerating Walls, various load combinations as specified in the Design Basis and Method Statement document are considered.

The critical load combinations for different segments of these walls differ from one another because of the individual wall location, width and height. The most critical load combinations which have been found governing the design of different segments in general terms are describe below. In each case, the design has been verified for performance under these critical load combinations. Table 4 summarizes the key results of these stability analyses.

8.0 CONCLUSIONS

The structural design analysis demonstrates that the Intake Approach and Accelerating Walls as designed and presented in this proposal submission are fully capable of withstanding the loadings under all operating conditions required for the project, based on the information provided in the proposal and relevant codes and practices.

More in-depth analysis during the detailed design stage will be required to finalize the design and to reflect new information obtained through investigations and research.
Appendix 1.1(s)
Appendix 1.1(s) - Draft Drawings

[See attached]
GENERAL NOTES

1.0 SCOPE OF WORK (INTAKE WORKS)

1.1 CONSTRUCT NEW ACCELERATING WALL

1.2 EXCAVATE INTAKE CHANNEL

1.3 EXTEND PIERS 1 AND 2 OF INTAKE STRUCTURE

1.4 CONSTRUCT INTAKE APPROACH WALL

1.5 REMOVE EXISTING ACCELERATING WALL

2.0 GENERAL

2.1 THESE DRAWINGS REPRESENT THE PRELIMINARY DESIGN OF THE WORK SCOPE WHICH MAY BE USED FOR BIDDING PURPOSE. MORE ACCURATE DETAIL DESIGN DRAWINGS WILL BE PROVIDED IN DUE COURSE.

2.2 THE GENERAL NOTES ARE APPLICABLE TO ALL PARTS OF THE INTAKE WORKS OF THE PROJECT AND SHALL BE READ IN CONJUNCTION WITH THE DRAWINGS AND SPECIFICATIONS.

2.3 THE CONTRACTOR HAS THE RESPONSIBILITY TO VERIFY ALL DETAILS AND DIMENSIONS OF THE EXISTING SITE AND ADJACENT STRUCTURES, AND TO OBTAIN ALL SITE DIMENSIONS. IF DURING THE COURSE OF WORK, COUNTER VARIATIONS ARE FOUND TO BE DIFFERENT FROM THOSE SHOWN, NOTIFY THE ENGINEERING CONSULTANT IMMEDIATELY BEFORE PROCEEDING WITH THE WORK.

2.4 DETAILS ARE SHOWN TO SHOW THE END RESULT OF DESIGN. ANY MODIFICATIONS TO SUIT FIELD DIMENSIONS AND CONDITIONS SHALL BE SUBMITTED TO ENGINEERING CONSULTANT FOR REVIEW PRIOR TO WORK.

3.0 FOUNDATIONS

3.1 INFORMATION REGARDING SUBSURFACE CONDITIONS AND ELEVATIONS ARE PROVIDED IN CONCEPT DRAWING NO. HSM130–DDE-2310–007 R3 PROVIDED BY ONTARIO POWER GENERATION.

3.2 FOUNDATION AREAS SHALL BE CLEANED OF LOSE, SOFT COMPRESSIBLE MATERIALS BEFORE PLACEING PRECAST CONCRETE MODULES.

3.3 PRECAST CONCRETE WALL MODULES MUST BE ACCURATELY LEVELLED AND POSITIONED TO ENSURE PROPER ALIGNMENT.

3.4 DETAILS OF FOUNDATION Contours MUST BE BROUGHT TO THE ATTENTION OF ENGINEERING CONSULTANT FOR POSSIBLE ADJUSTMENT OF DESIGN.

4.0 EXCAVATION

4.1 THE SIDES OF THE INTAKE CHANNEL EXCAVATION SHALL BE LINE-DRIED, AND CONTROLLED BLASTING SHALL BE EMPLOYED TO ENSURE THAT THE ROCK BEYOND THE EXCAVATION LIMITS IS NOT DAMAGE OR DESTABILIZED. ANY DAMAGED ROCK OUTSIDE THE REQUISITE EXCAVATION LIMITS SHALL BE REMOVED AND BACKFILLED WITH CONCRETE ADEQUATELY TIED BACK TO SOUND ROCK.

4.2 EXCAVATION OF THE INTAKE CHANNEL SHALL BE DONE IN TWO STAGES. THE FIRST STAGE CONSISTS OF EXCAVATION OF THE TWO SHALLOW APPROACH SECTIONS IN THE WET UP TO ELEVATION ±2.2. THE SECOND STAGE WILL BE DONE IN THE DRY CONDITION PROVIDED BY THE COFFERDAM.

5.0 GROUTING

5.1 THE CONTRACTOR SHALL BE RESPONSIBLE FOR THE SELECTION OF PIER AND COLUNN CEMENT TO ENSURE DEEPER EXCAVATING AREA IS SUFFICIENTLY DRY THROUGHOUT THE PERIOD FOR THE INTAKE CHANNEL EXCAVATION AND CONSTRUCTION OF THE CONCRETE INTAKE STRUCTURE.

6.0 CONCRETE

6.1 CONFORM TO THE REQUIREMENTS OF CSA STANDARD A23.1–00.

6.2 ALL CONCRETE TO BE FIELD TESTED IN ACCORDANCE WITH THE REQUIREMENTS OF A23.1–00 AND A23.2–00.

6.3 ALL CONCRETE IS TO HAVE THE SPECIFIED 28 DAY COMPRESSION STRENGTH, WATER CEMENTING MATERIAL RATIO, AND AIR CONTENT IN ACCORDANCE WITH THE REQUIREMENTS OF CSA STANDARD A23.1–00.

6.4 ALL CONCRETE SHALL BE NORMAL DENSITY CONCRETE AND CONFORMS TO THE FOLLOWING:

<table>
<thead>
<tr>
<th>LOCATION</th>
<th>EXPOSURE</th>

</table>

7.0 REINFORCING STEEL

7.1 ALL REINFORCING STEEL BARS SHALL BE DEFORMED AND SHALL CONFORM TO CAN/CSA STANDARD Z233-12M (2013).

7.2 REINFORCING STEEL SHALL BE GRADE 400 UNLESS OTHERWISE SPECIFIED.

8.0 BACK-FILLING

8.1 NO BACKFILL SHALL BE PLACED BEHIND THE CONCRETE APPROACH WALL UNTIL ROCKFILL HAS BEEN PLACED UP TO THE DESIGNED TOP LEVEL AND CAPPED WITH CONCRETE COVER SLAB.

8.2 BACKFILL MATERIALS ARE TO BE CLEAN, AND FREE OF DRAINAGE.

9.0 ROCK FILL

9.1 ROCK FILL MATERIALS TO BE PLACED WITHIN THE PRECAST CONCRETE CELLULAR WALL MODULES SHALL CONSIST OF CLEAN ROCK FRAGMENTS AND SHALL BE FREE FROM ORGANIC MATERIAL.

9.2 ROCK FILL SHALL BE REASONABLY UNIFORMLY GRADED IN SIZE UP TO A MAXIMUM OF 500MM AND SUCH THAT NOT MORE THAN 10% BY WEIGHT OF THE MATERIAL 25MM AND MORE THAN 50% BY WEIGHT SHALL CONSIST OF PARTICLES 300MM OR LARGER IN SIZE.

10.0 SEQUENCES OF CONSTRUCTION

10.1 IT IS ESSENTIAL THAT AT LEAST ONE ACCELERATION WALL IS IN PLACE AT THE EXISTING OR NEW LOCATIONS DURING THE NOVEMBER TO FEBRUARY PERIODS TO PROTECT THE STRUCTURE AND THE LOW WATER LEVEL EXISTING OUTSIDE THE WALL. THE CONTRACTOR SHALL ORGANIZE AND PLAN HIS WORK TO ENSURE THAT THE WALL IS COMPLETED WITH STRICTLY OR WILL BE RESPONSIBLE FOR ALL CONSEQUENCES RESULTING FROM HIS FAILURE TO DO SO.

10.2 REMOVAL OF EXISTING ACCELERATING WALL AND CONSTRUCTION OF THE NEW ACCELERATING WALL WILL BE COMPLETED PRIOR TO INSTALLATION OF THE COFFERDAM.

10.3 CONSTRUCTION OF THE INTAKE APPROACH WALL CAN BE DONE INDEPENDENTLY AT ANY TIME PENDING ON OTHER CONSTRUCTION CONSIDERATIONS.

10.4 EXTENSION OF THE PIERS 1 AND 2 OF THE INTAKE STRUCTURE AND PART OF THE WEST APPROACH WALL SHALL BE DONE IN THE DRY.

10.5 REMOVAL AND DISPOSAL OF THE GROUNFILL SHALL BE COMPLETED PRIOR TO REMOVAL OF THE INTAKE AREA COFFERDAM.

10.6 THE PRECAST FORMWORK FRAMES SHALL BE REMOVED AFTER THE SECTIONAL SERVICE GATES FOR THE INTAKE ARE IN PLACE AND WITH BALANCED WATER PRESSURE ON EACH SIDE OF THE GROUNFILL.

10.7 COMPLETION OF THE INTAKE WAVE WALLS AND BACKFILL IN THE WALL SHALL BE UNDERTAKEN AFTER THE REMOVAL OF THE ICE PROTECTION GROUNFILL AND COFFERDAM.

11.0 CONSTRUCTION NOTES

11.1 THE CONTRACTOR SHALL CARRY OUT SITE SURVEYS INCLUDING HYDROLOGIC SURVEYS TO DETERMINE THE EXISTING ELEVATIONS AND DRAINAGE BED AT THE NEW ACCELERATING WALL LOCATION.

11.2 THE CONTRACTOR SHALL VERIFY ALL ELEVATIONS AND DIMENSIONS OF THE EXISTING WORK AND ALL DETAILS ON SITE AGAINST THE CONSTRUCTION WORK AND REPORT ANY DISCREPANCIES TO THE ENGINEERING CONSULTANT BEFORE PROCEEDING WITH THE WORK.

11.3 THE CONTRACTOR SHALL REFER TO THE SET OF REFERENCE DRAWINGS PROVIDED BY OPG FOR DETAILS OF THE EXISTING STRUCTURES (NOW PIERS, EXISTING ACCELERATING WALL, EXISTING APPROACH WALL, ETC.)

11.4 FOR PERFORMANCE OF THE ABOVE WORKS IN THE INWALL PART OF THE PROJECT SITE, CONSTRUCTION ACTIVITIES WILL BE CO-ORDINATED CLOSELY WITH ONTARIO POWER GENERATION REGARDING ACCESS, WATER CONTROL, PERIOD OF TIME, ETC FOR ANY IN-WALL WORK.

11.5 THE CONTRACTOR IS RESPONSIBLE FOR DESIGN OF ANY TEMPORARY SHORING, AND THE STEEL CASING WITH ASSOCIATED STRUT SYSTEMS AS REQUIRED FOR THE BRIDGING COMPONENTS AND THE NOSE SECTION OF THE ACCELERATING WALL.

11.6 PRIOR TO THE PLACEMENT OF MASS CONCRETE IN-FILL, THE AREA SHALL BE CLEANED OF SILT AND DEBRIS.

11.7 WHEN THE MASS CONCRETE IN-FILL AREA CANNOT BE KEPT WATERTIGHT, PROCEDURES FOR UNDERWATER CONCRETING SHALL BE ESTABLISHED TO INCLUDE CONCRETE MIX DESIGN, APPROPRIATE ADJACENCY, PLACEMENT SCHEMES, INSPECTION PLAN, AND CONCRETE SAMPLING PLAN TO ENSURE COMPETENT CONCRETE IS ACHIEVED. WHEN THE CONCRETE SURFACE HAS BEEN Brought ABOUT THE WATER LINE, REGULAR CONCRETE SHALL BE PLACED IN THE DRY AFTER ALL THE LATANCE HAS BEEN REMOVED FROM THE SURFACE OF THE CONCRETE.

11.8 FOR EXTENDING THE PIERS, DEMOLISHING CONCRETE SURFACES SHALL BE THOROUGHLY SCALPED, AND PRIOR TO THE PLACEMENT OF NEW CONCRETE, THE ENTIRE SURFACE OF THE EXISTING CONCRETE SHALL BE THOROUGHLY CLEANED BY SANDBLASTING, FOLLOWED BY A AIR-WATER JET TO REMOVE ALL LOOSE AND ADHESIVE CONTAMINATING MATERIAL TO ENSURE FULL BONDING.

11.9 ALL REINFORCING STEEL ANCHORS INTO ROCK WILL BE INSTALLED USING EITHER CEMENTOUS OR RESIN-TYPE GROUT WITH PROCEDURES RECOMMENDED BY THE MANUFACTURER.

11.10 THE CONTRACTOR SHALL ADHERE TO ALL ENVIRONMENTAL REQUIREMENTS AND PRESCRIBED WORKING CONDITIONS NOTED ON PERMITS AND APPROVALS FROM AGENCIES IN CONSTRUCTION OF THE EXISTING TEMPORARY AND PERMANENT WORK.

12.0 DEWATERING STRUCTURE AT PUMP GENERATION STATION (POS)

12.1 FOR REMOVAL OF DEWATERING STRUCTURE AT POS REFER TO AS-BUILT DRAWING PROVIDED BY ONTARIO POWER GENERATION.

13.0 QUANTITIES

13.1 THE CONTRACTOR SHALL USE THE MOST UP-TO-DATE QUANTITY ESTIMATES ASSOCIATED WITH THESE DRAWINGS FOR BIDDING PURPOSE. THESE QUANTITIES REPRESENT THE WORK COMPLETED AT A PRELIMINARY DESIGN STAGE, BASED ON DESIGNED INFORMATION PRODUCED AND DIRECTIONS RECEIVED FROM THE CONTRACTING TEAM, AND WILL BE SUBMITTED TO MODIFICATION AND UPDATING AS THE DETAILED DESIGN AND CONSTRUCTION ARE PROCEEDED.

ELEVATIONS ARE IN METRES AND ARE BASED ON NAVD SYSTEM.
GENERAL NOTES

1.0 THE CONTRACTOR SHALL BE RESPONSIBLE FOR MEETING ALL THE ENVIRONMENTAL REQUIREMENTS REGARDING IN-RIVER WORK AND DISPOSAL OF MATERIALS REMOVED FROM THE SITE.

2.0 CROSS-SECTIONS SHOWN IN THIS DRAWING ARE BASED ON TYPICAL CRIBS FOR ILLUSTRATION PURPOSES ONLY. THE CONTRACTOR SHALL REFER TO THE SET OF REFERENCE DRAWINGS NO. NF/PA-F-4206 REV 4, NF/PA-F-4275 REV 0, AND NF/PA-F-4278 REV 0 PROVIDED BY OGPS FOR OTHER RELEVANT DESIGN DETAILS OF THE EXISTING ACCELERATING WALL.

3.0 THE CONTRACTOR HAS THE RESPONSIBILITY TO CONDUCT FIELD SURVEY AND INSPECTION OF THE EXISTING STRUCTURE TO VERIFY ALL DETAILS AND DIMENSIONS NECESSARY IN PLANNING AND EXECUTION OF THE REMOVAL WORK.

CONSTRUCTION NOTES

1.0 MEANS AND METHODS USED IN DEMOLITION OF THE EXISTING ACCELERATING WALL SHALL BE SUCH AS TO MINIMIZE IMPACT ON THE OPERATION OF THE RIVER. ALL IN-RIVER ACTIVITIES SHALL BE CO-ORDINATED WITH ONTARIO POWER GENERATION.

3.0 ALL STRUCTURAL MATERIALS OF THE EXISTING WALL SHALL BE REMOVED FROM THE NADARA RIVER. ROCK FILL MATERIALS OF GOOD QUALITIES MAY BE RE-USED FOR CONSTRUCTION OF THE NEW ACCELERATING WALL SUBJECT TO THE APPROVAL OF THE ENGINEERING CONSULTANT AS WELL AS ONTARIO POWER GENERATION.

2.2 Tunnel Boring Machine Special Features For the Niagara tunnel facility Project

- Cutterhead designed with an inner section and four (4) outer cutterhead sections with 17” front loading/back-loading cutter housings, and grill bars in bucket openings for blocky ground.
  - Cutterhead with minimum peripheral exposure
  - Cutterhead stand off 150mm
  - Cutterhead using replaceable abrasion resistant wear bars
  - Cutterhead with smooth low cutter profile and radial muck scoops with shallow relief, direct dump buckets for improved face control and reduced raveling at the gauge bucket lips are bolted on for easy replacement.
- High capacity 3-axis roller main bearing for sustained operation at high thrust with long life, L 10 ≥ 15,000 hours.
- Excess capacity to handle extreme ranges of hard and blocky rock, water conditions, and ground support installation.
- 17” cutters help to minimize the effects of hard abrasive rock while maintaining high production rates and allowing fewer cutter changes.
- Large open area behind cutterhead for ground support.
- Cutterhead is Variable Frequency Drive (VFD), is fully reversible and allows increased torque at startup. Muck pick-up is one direction.
- Large, articulated oversize gripper pads to reduce gripper ground pressure in areas of weak, fractured, unstable rock to reduce fallout of material.
- Slotted gripper pads to allow gripping over ring set.
- Large work area under main beam for cleaning and water draining.
- Continuous steering system, while boring, to maintain line and grade as required.
- Hydraulic roof support offers immediate rock support at the rear of the shield “fingers” with full support to protect the workers.
- Ring Beam Erector for preferred ring beams profile
- Wire Mesh - wire mesh handling and erection system
- Two sets roof drills with independent control and bolting while boring, coverage is 180° of crown.
- Two sets probe/grout drills dedicated to 360° probing and grouting mounted on a circular support.
- TBM muck removal system with excess capacity to allow high peak rates of advance.
- Water protection for electrical and hydraulic systems IP55.
- Dust control system to confine dust to the cutter face and maintain a good work environment.
- Data Logger with remote monitoring
- Dual laser target system to permit continuous steering control and monitoring of line and grade. Electronic guidance system allows precise guidance information, including interface unit + laser theodolite.
- Water spray system or foam for dust control.
- Equipment monitoring instrumentation displayed at the operator’s console to allow speedy fault finding and correction actions.
- Methane gas monitor auto shut down of TBM if acceptable levels are exceeded.
- Class I – Div II electrical system and Class I – Div I for essential services.
- Ground fault protected electrical system standard on all Robbins TBMs.
- High powered proven TBM design, “classic” main beam open gripper.
Appendix 1.1(aa) - Flow Verification Test

1. **PURPOSE OF TEST**

   (1) A flow verification test (Test) shall be conducted to determine the as-constructed flow amount of the Tunnel Facility Project in order to determine if the Guaranteed Flow Amount is achieved.

2. **TEST METHOD AND ACCURACY**

   (1) The Test shall be conducted using the tracer transit time method and a non-radioactive, non-salt tracer. The following test standards shall be used as the bases for the tests and as otherwise indicated in this Appendix:

      (a) International Electrotechnical Commission IEC 41-“Field acceptance tests to determine the hydraulic performance of hydraulic turbines, storage pumps and pump-turbines”

   (2) Locations for the tracer injection points are at the tunnel intake or at one of the tunnel piezometer wells. Tracer samples may be taken along the tunnel using the equipment installed in the piezometer wells, the dewatering shafts and/or at the tunnel outlet.

   (3) The unique features of the new tunnel (i.e., having very large cross sections and high water velocities) may make the use of multi-port tracer injection and detection frames impractical. Therefore, provision for adequate mixing of the dye prior to the first sampling location shall be made.

   (4) Transit time measurements shall be determined from two sampling points.

   (5) The maximum uncertainty (including the random and systematic errors) for the flow measurement shall be +/-2%.

3. **PARTY TO CONDUCT THE FLOW TEST**

   (1) The Test shall be conducted by an independent third party, mutually acceptable to the Owner and the Contractor (the “Independent Tester”) which has significant experience and has carried out flow testing using the tracer methods in closed conduits of similar complexity. The Independent Tester shall be retained by the Contractor as an independent tester for and on behalf of both the Contractor and Owner. The Independent Tester shall be impartial in all respects. Prior to entering into an agreement with the Independent Tester to perform the Test and the related matters described in this Appendix 1.1(aa) (the “Independent Tester Contract”), the Contractor shall deliver to the Owner a copy of the proposed
agreement for review and approval by the Owner. The Contractor shall be responsible for management of the Independent Tester and the Owner and the Contractor shall each be responsible for 50% of all of the costs and expenses properly incurred by the Independent Tester in accordance with the Independent Tester Contract. After receipt of an invoice from the Independent Tester, the Contractor shall be permitted to include 50% of such invoice amount as part of any Application for Payment submitted by the Contractor to the Owner.

(2) Within 6 months after the Start Date, the Independent Tester shall deliver to the Contractor and Owner:

(a) preliminary details of Test procedure;

(b) preliminary details of Test setup and proposed equipment descriptions; and

(c) preliminary details of Test uncertainties (i.e., expected random and systematic errors).

(3) Owner and the Contractor shall have the right to review the proposed preliminary details of Test procedure, preliminary details of Test setup and proposed equipment descriptions and preliminary details of Test uncertainties and, if necessary, make recommendations to the Independent Tester to modify the preliminary details of Test procedure, the preliminary details of Test setup and proposed equipment descriptions and the preliminary details of Test uncertainties.

4. TEST SCHEDULE

(1) The exact Test date and time of performance of the Test requires extensive planning among several parties and also depends on the water availability. Therefore, the Test date and time will be decided by the Owner at its sole discretion. The Owner will make all reasonable efforts to have the test conducted as soon as practically possible following Substantial Completion, preferably within 2 weeks. Prior to Final Completion, the Test must be performed and the final Test report must be delivered to the Owner and the Contractor, all as more particularly described in Section 10 of this Appendix 1.1(aa) 1.1(aa).

5. TECHNICAL BASIS OF TESTING

(1) During the Test, the Owner’s operators at the existing SAB Control Room (“SAB Operations”) will attempt to maintain the water levels at a steady state. The hydraulic head on the tunnel conveyance system will be defined as the difference between the elevations of the energy grade line (EGL) at Section 1 (at the intake water surface gauge, in the vicinity of the tunnel intake structure) and Section 2 (at the outlet water surface gauge, in the tunnel outlet canal, immediately upstream from the transition at the junction with the PGS channel). The locations of the gauges are generally as shown on the Concept Drawings.
The Guaranteed Flow Amount (GFA) is specified for the following reference hydraulic head ($H_{ref}$) and the reference elevation of the energy grade line at Section 2 ($EGL_{2ref}$):

$$H_{ref} = 5.60 \text{ m}$$

$$EGL_{2ref} = 165.20 \text{ m (NAD83)}$$

The reference elevation of the energy grade line at Section 1 ($EGL_{1ref}$) will be defined by Equation 1.

$$EGL_{1ref} = EGL_{2ref} + H_{ref} \quad (1)$$

For the purposes of the Test, at Section 1, the velocity head will be assumed to be zero and the hydraulic and energy grade lines considered as equal.

During the Test, the following three values will be measured to evaluate the hydraulic performance of the tunnel:

(a) the measured flow, $Q_m$ (m$^3$/s) as determined by the tracer transit time method as specified in Section 2 of Appendix 1.1(aa);

(b) the hydraulic grade line elevation at Section 1, $HGL_{1m}$ (m) as measured at the intake gauge; and

(c) the hydraulic grade line elevation at Section 2, $HGL_{2m}$ (m) as measured at the outlet gauge.

The stipulated energy grade line elevation, $EGL_{2ref}$, will have a corresponding calculable hydraulic grade line elevation, $HGL_{2ref}$, corresponding to the guaranteed flow, GFA. During testing, an effort will be made to match the measured hydraulic grade line elevation, $HGL_{2m}$ to the reference value $HGL_{2ref}$. However, it is recognized that there will be some difference between the level achieved and the reference level. During testing, the measured value must be within $\pm 0.3$ m of the reference value.

**DETERMINATION OF REFERENCE TUNNEL FLOW**

The measured tunnel energy grade line elevations at Sections 1 and 2 will be calculated by the following formulae.

$$EGL_{1m} = HGL_{1m} \quad [2]$$

$$EGL_{2m} = HGL_{2m} + \left(\frac{Q_m}{A_{chan2}}\right)^2 \quad [3]$$
\[ A_{chan2} = (HGL_{2m} - invert_2) \times w_{chan2} \]  

where

\( A_{chan2} \) = cross-sectional area of the channel at Section 2

\( invert_2 \) = invert elevation at Section 2

\( w_{chan2} \) = width of the channel at Section 2

(2) The discharge that would have been obtained, had EGL_{1ref} and EGL_{2ref} been obtained, is \( Q_{ref} \), calculated as follows:

\[ Q_{ref} = Q_m \times \sqrt{\frac{H_{ref}}{EGL_{1m} - EGL_{2m}}} \]

7. TEST PREPARATION

(1) The Independent Tester shall submit the final detailed Test procedure to the Owner and the Contractor for review and acceptance, a minimum of one (1) year prior to the expected Test date.

(2) At least six (6) months prior to the Test, the Independent Tester shall design, prepare and complete an equipment verification test to ensure that the equipment and methodology meet the requirements of the Test. The Independent Tester shall provide sufficient notice to the Owner and the Contractor for their review and acceptance of the equipment verification test and to ensure their availability to witness the testing.

(3) The Contractor will obtain the necessary Approvals to conduct the test a minimum of three (3) months prior to the expected Test date.

8. TEST SETUP

(1) The Test setup shall be designed by Independent Tester and constructed and installed by the Contractor, with oversight by the Independent Tester.

9. TEST PROCEDURE

(1) The following list describes the main steps of the Test procedure. The Independent Tester may make prudent changes which reduce the uncertainty of the measurements, subject to the concurrence of the Owner and the Contractor.

(a) Prior to the Test time, the SAB water diversion system will be brought as close to a steady-state condition as practical by SAB Operations as indicated in Section 5 above and maintained as practically as possible at the steady-state water levels for a minimum of three hours. During this
period, the SAB PGS will not be operated and the gates of the INCW within the Ice Acceleration Channel will be in closed positions.

(b) The Test will start as soon as the Independent Tester is satisfied with the test conditions. The transit time of the tracer is expected to be about 40 minutes or less. The tracer will be injected a minimum of five times in accordance with ISO 2975, Part VI, Section 5.5 (i.e., minimum of five test runs) under the same steady state flow conditions. The Independent Tester will record the test data for each Test run (i.e., tracer time and tracer distributions at the injection and detection points).

(c) If the Independent Tester is not satisfied with any of the Test runs, he may cancel that Test run in his sole discretion. In this case, the Independent Tester shall exclude the results of such cancelled Test from the Test report and shall provide an explanation for the cancellation in his Test report.

(d) If the Independent Tester is not satisfied with any aspect of the execution of the Test, he shall submit a written request to the Owner and the Contractor within 24 hours of the test completion to repeat the Test. Upon receiving the request, the Owner will use all reasonable efforts to manage SAB Operations so as to allow the Test to be repeated as soon as possible.

(e) The Owner and Contractor each have the right to witness the Test at their own costs.

10. TEST REPORT

(1) The Independent Tester shall submit the preliminary Test results to the Owner and the Contractor within five (5) Business Days of the test completion. The Independent Tester shall submit copies of the final Test report to the Owner and the Contractor (three copies to each party) within the following 15 Business Days. The Test results shall be presented in the metric SI of units.

(2) The Test report will include the following:

(a) Test objectives

(b) records of all agreements pertinent to the Test

(c) personnel taking part in the Test

(d) description of the Test program

(e) description of the Test setup (including but not limited to the serial numbers and calibrations of the Test equipment)

(f) description of the Test procedure
Appendix 1.1(aa) - Flow Verification Test - Page 6

(g) description of the Test results
(h) complete set of Test readings
(i) measured tunnel flow ($Q_{Test}$) for each Test run
(j) intake gauge and outlet gauge elevations ($HGL_{1m}$ and $HGL_{2m}$) averaged over each Test run period
(k) an evaluation of the random and systematic uncertainties of each measured quantity and a calculation of the total uncertainty of data derived from combined measurements for each Test run
(l) statement regarding cancellation of any Test runs.

11. IMPACT OF WATER QUALITY AND WATER TEMPERATURE

(1) The Owner and the Contractor agree that the effects of the water quality, water temperature and seasonal flow variations on the flow Test results are negligible and will not be considered. The Owner and the Contractor also agree that the flow measurements will not be corrected to compensate for the temperature and pressure changes inside the tunnel when the tunnel is filled with water.

12. ANALYSIS OF TEST RESULTS

(1) The Test results shall be analyzed in accordance with the approach given in Section 6 above.

(2) The numerical average of the reference flows (Average $Q_{Ref}$) of all Test runs completed to the satisfaction of the Independent Tester shall be deemed to be the Performance Test Water Flow Amount (PTWFA) for the purposes of Section 8.3 of this Agreement.

(3) Calculations are to carry all significant figures. No rounding of values is to be done until the final calculation of Average $Q_{Ref}$. This value should be rounded to the nearest 0.1 m$^3$/s based upon the following rules:

(a) when the digit to be dropped is less than five, write the number without the digit; example, 505.844 becomes 505.8

(b) when the digit to be dropped is greater than five, the preceding digit is increased by one; example, 505.86 becomes 505.9

(c) when the digit to be dropped is exactly five, then the nearest even number is used for the preceding digit; example, 505.85 becomes 505.8.
13. **FINAL AND BINDING**

Provided that the Independent Tester follows the procedures and standards set out in the Appendix 1.1(aa), the Test results, calculations and other determinations of the Independent Tester are final and binding on the Owner and the Contractor and not subject to review by or reference to the DRB or any appeal.

14. **CORRESPONDENCE**

All recommendations, acceptances and approvals provided to the Independent Tester shall be mutually agreed by the Contractor and the Owner. In the event that the Contractor and the Owner do not agree as to a recommendation, acceptance or approval, the Independent Tester shall consider the positions of each of the Owner and the Contractor and shall proceed in the manner it considers appropriate in the circumstances. To the extent that either the Contractor or the Owner provides the Independent Tester with written instructions or directions, a copy of such instructions or directions shall be concurrently provided to the other party.

Appendix 1.1(nn) - INTENTIONALLY DELETED
Appendix 1.1(qq)
Appendix 1.1(qq) - OPG’s Delegation Notice

DELEGATION OF AUTHORITY
(or change in delegation of authority)

To: Strabag AG (the “Contractor”)

Contract: Design/Build Agreement dated 2005, between the Contractor and Ontario Power Generation Inc. (“OPG”)

Delegation No.:  
Date:  

Defined terms used in this Notice have the same meanings given to those terms in the Agreement. In accordance with Section 3.2 of the Agreement, OPG hereby notifies the Contractor that OPG’s Representative is  

The duties of OPG’s Representative are delegated to the individuals named below for the subject matters and subject to the limitations set out in this Notice. These delegations will continue in full force until revoked by OPG in another delegation of authority Notice.

1.0 OPERATIONS – FOR OUTLET ONLY

Preliminary

1) The contractor will remove the overburden along the footprint of the outlet channel, as depicted in the drawings and cross sections. This overburden will be temporarily stored in the materials yards.

2) The contractor will construct the channel outlet to the rock plug limit by means of rock excavations. The rock that is found to be reusable (estimated at ~ 140,000 M3) will be crushed and reused in:
   - Access road construction
   - Backfill as required in the inlet structural drawings.

3) The overburden that is found to be reusable will be used in constructing the entrance road into the outlet opening. The excess overburden from note #1 above will be removed to the designated disposal site by truck.

Operational Stage

1) Excavated material from the Outlet area is to be loaded on Conveyor 1 and removed to the Temporary Stockpile1. This will facilitate initial aeration2 and discharge of contaminants into the runoff pond. The excavated material will be inspected to ensure that no contaminants were introduced during the tunnel boring process. The size of the temporary stockpile will accommodate the material produced by 15 days of tunnel boring, or ~51,000 m3.

2) After it is determined that the material has no BTEX or other contaminants, it will then be transported to the Material Distribution Pile through Conveyor 2. Conveyor 2 will bridge across the HEPC Canal. This stretch of the conveyor has to be covered/protected to prevent any passage of material into the North HEPC canal.

3) The material will be distributed along the area between the two HEPC canals (designated disposal area), using rock trucks, and in accordance with the drawings and cross sections provided in the materials quantity sheets. The material will be compacted in order to minimize air voids, and in order to minimize the possibility of water infiltrating the bottom layers of the pile and destabilizing it3.

4) Ground water will be pumped into a retention pond capable of holding ~45,000 m3 of water. The water will pass through a lamella clarifier before being discharged into the north HEPC canal. Water (either ground water trapped in rock or runoff) from the temporary stockpile runoff pond will be fed directly into the clarifier.

---

1 Conveyor belt to be constructed by STRABAG. It will be able to move 1,200t/hour of material as peak design load
2 Certain rock formations (description given in OPG Baseline Geotechnical report) contain BTEX contaminants.
3 Due to the characteristics of Queenston Shale – becomes a slippery clay like material when exposed to water
5) Storm water runoff from the material distributed in the designated disposal area will be collected via ditches in a settling pond (location depicted on OCA drawing). Disposal of runoff can be done in two ways (based on environmental approvals):

- Discharge the contents of the pond through filter cloth into the North HEPC canal (preferable)
- Pump the contents of the pond into tanker trucks and deliver the water to the ground water retention pond, where they will be treated by the clarifier.

**Post Construction**

1) The material berm at the designated disposal area will be top soiled, sodded and trees will be planted on it in order to prevent long-term erosion.

2) Materials yards, offices yards, retention pond will be restored to their pre-construction stage, including vegetation and trees.

3) The impervious liner of the temporary stockpile will be disposed of in an approved disposal site. The ground will be restored as noted above.

**2.0 CONTINGENCY PLANS AND SUBSTITUTES**

1) Break down of Conveyor Belt #1 – Material can be removed from the tunnel exit by trucks via Rd. “E” and Rd. “D” to the temporary stockpile.

2) Break down of Conveyor Belt #2 – Material can be removed from the temporary stockpile by trucks via access roads “C”/“B’ and access 1. The temporary stockpile will be capable of retaining 15 days of spoils production.

3) Breakdown of Clarifier – Retention pond deemed capable of holding sufficient water volume pending repair. However, additional pond can be constructed adjacent to it in materials yard No. 2.

4) Exiting natural ravine unable to cope with increased storm water runoff quantities. Excavate a retention pond in materials yard #1 to supplement the existing pond.

**3.0 SPECIAL PROVISIONS**

All clauses in all the relevant OPS Specifications and OPG Owner’s Mandatory Requirements (Appendix 1.1 uu) are to be read in conjunction with this document except the BASIS OF PAYMENT, wherein the General Conditions pertaining to MEASUREMENT AND PAYMENTS shall be applicable.

---

4 Increasing the size of the existing pond is not desirable, as the pond requires heating in winter.

5 Due to the striping of topsoil and the increase in paved areas.
3.1 GENERAL ITEMS

G.1 Construction Facilities and Temporary Control

Before commencing construction operations, supply, erect and maintain hoarding around entire perimeter of Site as shown on the drawings. Mark with "POST NO BILLS" signs on the outside of the hoarding. Remove hoarding upon Contract completion unless as directed by the Commissioner.

Prevent unauthorized entry to the Site. Barricade, guard, or lock access points to the satisfaction of the Engineer and post "NO TRESPASSING" signs.

Provide barriers around trees and plants designated to remain. Protect from damage.

Provide secure, rigid guide rails and barricades around deep excavations, open shafts, open stair wells, open edges of floors and roofs as required for protection of Work, workers, and the public.

Provide Utilities including lighting and water supply to the construction site. The Contractor shall be responsible for payment of these services including the installation/removal of meters and work associated with connection and disconnection. Washroom facilities shall also be provided by the Contractor.

Protect surrounding private and public property from damage during performance of the Work. Take precautions to prevent fires. Provide and maintain temporary fire protection equipment of a type appropriate to the hazard anticipated in accordance with authorities having jurisdiction, governing codes, regulations, by-laws and to the satisfaction of the Engineer and insurance authorities.

Workers shall comply with the Occupational Health and Safety Act and Regulations for construction projects.

Supply and install offices at the site for the duration of the Work in locations as indicated on the drawings. Provide offices with electric light, heat, air conditioning, telephone and first aid equipment as required by the Workplace Safety and Insurance Board and the Ontario Ministry of Labour. Office shall have adequate electric heating, air conditioning and lighting; washroom and water closet with hot and cold running water and supplies; and labour for daily cleaning of the washrooms and offices. Equip the offices with the following: desks and chairs, tables with drawers, plan table and drafting stool, aluminum wall mounted plan racks and lockable fireproof fire cabinets. Provide and pay for the telephone services with “call answering” and a paper facsimile machine on a separate dedicated phone line for the facsimile machine. Also provide a photocopier capable of making multiple copies up to 11” x 17” in size, complete with sorting capabilities. Provide regular service for fax and photocopy machine for the duration of the Work. All trailer windows must be protected with metal bars and all doors to have metal plate with padlock capability. For all trailers and temporary buildings, provide wood stairs, platform and boardwalk, painted and repainted as required with non-skid abrasive paint.

Remove temporary offices (buildings) upon Contract Completion. Restore area(s) to match the existing surrounding areas.
Maintain the Site and adjacent areas in a clean and orderly condition, free from debris and other objectionable matter. Remove rubbish and surplus material, equipment and structures immediately. If the Site is not cleaned within 48 hours after the Contractor has been instructed to do so, the Engineer may clean the Site and retain the cost from monies due, or to become due, to the Contractor.

Keep haul routes free at all times from materials spilled on street surfaces and maintain streets in clean condition to the satisfaction of the Engineer and the street authorities.

During the progress of the Work, afford access to visitors duly authorized by the Engineer and facilitate inspections or tests they may desire to make. Ensure Site visitors wear appropriate safety apparel.

The Contractor shall provide water trucks for dust control as where required.

G.2 Examination, Protection and Restoration of Property

The Contractor shall examine, protect and restore if damaged by the execution of the Work, all property adjacent to the Work or that may be affected by the Work, including all equipment and services within the properties.

The Contractor, the Commissioner and the structure owner shall jointly examine each of these properties prior to the start of construction. Amendments to the inspection reports, if required, will be carried out by the Commissioner. The reports shall then be signed by all three parties.

The Contractor, the Commissioner and the structure owner shall jointly re-examine each of these properties after construction is completed to record condition differences.

The restriction of joint examination to specific properties does not relieve the Contractor of its responsibility for the examination, protection and restoration of all property adjacent to the Work or which may be affected by the Work.

Locate, protect, support and maintain all equipment and services affected by the Work.

The Contractor shall fully secure the integrity of the foundation of the INCW prior to any blasting work.

On completion, restore equipment and services to their original condition, and relocate where necessary, to the satisfaction of the Engineer.

Repair and restore any part of the property including equipment and services broken or damaged by operations performed under the Contract.

G.3 Safety

For the purposes of the Contract, the term "constructor", as defined in the Occupational Health and Safety Act, shall mean the Contractor who shall be responsible for ensuring that the provisions of the statutes, regulations and by-laws pertaining to the duties, obligations and safe
performance of the Work in accordance with the obligations of the "constructor" as set out in the Occupational Health and Safety Act are to be observed.

Regardless of whether the Commission or the Contractor pursuant to the Occupational Health and Safety Act as the "constructor", the Contractor's representative shall be responsible for ensuring that the provisions of statutes, regulations and by-laws pertaining to safe performance of the Work are observed and that the methods of performing the Work do not endanger the personnel employed thereon and the general public, and are in accordance with the latest edition of the Occupational Health and Safety Act.

Prior to the Contractor's representative being absent from the Site, the Contractor's representative will name another person, in writing to the Commissioner, who is competent to assume these responsibilities. The Contractor shall advise the Engineer of any change in the individual identified as the Contractor's representative.

The Contractor's representative shall ensure that all measures and procedures prescribed by the following Acts and Regulations are carried out on Site and every employer and every worker performing work on the Site complies with all of the requirements:

- The Occupational Health and Safety Act;
- The Regulations for Construction Projects;
- WHMIS Regulations;
- The Environmental Protection Act and regulations,
- Dam Safety Regulation under the Lakes and Rivers Improvement Act;
- All other legislation, regulations and standards as applicable.

During underwater construction, in-service inspection and maintenance of the structures, safety of the divers or personnel shall ensured.

G.4 Traffic

Conduct the Work in such a manner as to ensure the least interference with pedestrians, cyclists and vehicular traffic. Comply with arrangements made with traffic and police authorities and as directed by the Engineer.

Give the Engineer seven (7) calendar days written notice of desire to restrict or close any street or lane permitted under the Contract. Do not put any restriction or closure into effect without the approval of the traffic and police authorities and the Engineer's written approval.

Under the direction of the police and traffic authorities and in accordance with the Manual of Uniform Traffic Control Devices, supply, erect, maintain, and subsequently remove signs, signals, flasher beacons and delineators, which are required by the traffic authorities for the diversion and guidance of vehicular and pedestrian traffic.

Haul routes and the location of any ramps which enter onto any street are subject to the written approval of the Engineer, traffic and police authorities prior to the start of any Work. No ramp may be placed in an area where future construction is planned.
Keep haul routes free at all times from materials spilled on street surfaces and maintain streets in a clean condition to the satisfaction of the Commissioner and authorities having jurisdiction.

The Commissioner may inspect haul routes, the Site and adjacent premises daily and may halt operations, withhold payment or carry out such additional operations as necessary, deducting the cost from monies due, or to become due.

Access and egress to and from the Site shall be at the locations shown on the Contract Drawings.

Maintain access roads, sidewalks, ramps, construction runways and decked areas adjacent to the Site in a safe condition throughout the Contract.

Take precautions to avoid tracking and depositing materials, debris and mud on roads and on the Owner’s property from vehicles and equipment operating to and from the construction Site, and be responsible for removal of such deposits by brooming and washing to the satisfaction of the Commissioner.

Maintain access routes, sidewalks, Site roads, trailer area, storage areas as well as Work areas free of ice and snow to maintain safe operating conditions and to maintain progress of the Work. Cleared snow shall be removed from the Site within 12 hours of a snow fall or as directed by the Commissioner.

4.0 ELECTRICAL AND MECHANICAL WORKS ITEMS

4.1 E&M.1 INTAKE AND OUTLET GATES

Under this item, the Contractor shall supply, deliver and install new Intake Gates including all hardware, inserts in concrete, trial operations and delivery to storage as prescribed by OPG. Also included in this item is New Outlet Gates including all hardware, inserts, fabrication, delivery and installation including all lift and full scale trials as requested.

This item also included New Outlet Gates supporting structures are as part of the outlet gate installation.

4.2 E&M.2 SITE ILLUMINATION (TEMPORARY)

4.3 E&M.3 SITE ILLUMINATION (PERMANENT)

4.4 E&M 4 PROVISIONS OF POWER TO SITES

5.0 CIVIL WORKS ITEMS

C.1 CHAIN LINK FENCE

Under this item, the Contractor shall supply and install new approved chain link fence, foundation and associated components (fence, posts, connection hardware, etc) at the following locations:
1. At the Intake Site Area where around possible addition of construction/stockpiling areas as shown on the drawings.

2. Various locations at the Outlet Site Area at specified on the drawings including site offices, restricted woodlands, restricted meadow, Area North of HEPC canals, Adjacent to Whirlpool Rd and Materials Yard 1.

The chain link fence shall meet the requirements of OPSS No. 541 except as specified herein.

The total height of the chain link fence shall not be lower than 2.50 m and the height of the chain link fence on grade shall not be lower than 2.30 m. Lockable gates shall be provided as shown on drawings.

**C.2 CLEARING AND GRUBBING (150 MM THICK)**

Under this item, the Contractor shall clear and grub the existing ground areas as required to gain access for equipment, materials and personnel, to the work area at both Intake and Outlet Site Areas.

This item shall meet the requirements of OPSS No. 201 and 206 except as specified herein.

This item will be deemed to have included for the removing, carting away and disposing of all vegetation including removal of topsoil from the work zone except for mature trees, which have to be identified prior to the commencement of this operation and relocated as per the directions and sole discretion of the Project Manager. Also prepare the surface ready to commence the permanent works. Mature trees are to be relocated to pre-determined locations. Topsoil is to be stockpiled in a predetermined location for future use.

Prior to any clearing and grubbing, a professional arborist shall be retained to review any tress that the Contractor deemed necessary for relocation. Trees relocation shall be paid elsewhere.

Under this item, the Contractor shall regrade all surfaces affected by construction to original condition or better.

**C.3 SILT FENCE**

Under this item, the Contractor shall supply and install new silt fence barrier and associated components along the southern edge of the access road adjacent to North Canal and Final Disposal Area at the Outlet Area to prevent passage of material into the waterway as shown on the drawings.

This item shall meet the requirements of OPSS No. 577 and as specified herein.

The specification should be read with particular emphasis on Clauses 577.07.02 and 577.07.03 for construction of the Silt Fence and Clause 577.07.12 for sediment removal and management. Throughout the period of the contract the fence should be serviced and maintained as to fulfill the purpose of its erection.
A 100m stand-by supply of prefabricated silt fence barrier shall be maintained at the site throughout the duration of the contract.

C.4 IMPERVIOUS LAYER IN CERTAIN AREAS

This item shall meet the requirements of OPSS No. 1205 and as specified herein.

In the Temporary Stockpile and Run-Off Pond locations, an impervious membrane has to be provided to prevent percolation of contaminants into ground water. The layer used can be built up or be off the market with the prior approval of the Project Manager.

C.5 EXCAVATION

Under this item, the Contractor shall carry out all required excavation to profiles, specified in the respective drawings, stockpile and disposal of the excavated material (rock and earth) at both Intake and Outlet Site Areas including the Access Ramps to Intake Elevation and to Outlet Entrance during Construction as indicated on the drawings. Excavated material to be used as ‘fill’ wherever applicable or removed to the designated disposal area.

The sides of the intake channel excavation shall be line-drilled and controlled blasting shall be employed to ensure that the rock beyond the excavation limits is not damaged or destabilized.

Ground water retention pond to be excavated and the excavated material to be placed and compacted in lifts all around to form the water retaining structure as per details provided in the drawings.

The Run-off pond will be excavated as shown in the drawings and will be lined with an impervious layer/membrane to prevent percolation of contaminants into the ground.

The overburden along the path of the outlet channel will be excavated as shown in the drawings and cross sections. Some of the overburden will be reused in constructing the access road into the outlet shaft. The rest will be removed to the designated disposal area via trucking.

The designated disposal area will be surrounded by a ditch and a silt fence, in order to trap sediment and prevent it from accessing the HEPC canals.

This item shall meet the requirements of OPSS 102, 206, 212 and 1010.

Side slopes of the excavation areas shall be keep to 2H:1V or provide stabilized structure such as roadway protection, earth retaining systems otherwise.

Any damaged rock beyond the excavation limits shall be removed and backfilled with concrete adequately tied back to sound rock at Contractor’s own expense.

All the excavation limits datum was based on the information and drawings supplied by the OPG.
As part of the work, the Contractor shall indicate the location of any buried utilities by stakeouts prior to any excavation and those utilities shall be protected/relocate at all time during excavation and construction.

C.6 NATIVE FILL

Under this item, the Contractor shall pick-up, transport, place, and compact the stockpiled material that was selected and removed from the site at both Intake and Outlet Areas as indicated on the drawings.

This item shall meet the requirements of OPSS 902, 1010 and 1501.

The Contractor shall confirm the top of backfill material elevations to the required elevations for the Commissioner to review prior to the work.

C.7 GRANULAR ‘B’

C.8 GRANULAR ‘A’

Under Item C.8, the Contractor shall supply, deliver, place and compact granular materials ‘B’ at the following locations to the extent shown on the drawings.

1. Access roads at both Intake and Outlet Areas to the depth as indicated.
2. Areas behind the East and West Approach Walls to the elevations as indicated.

Under Item C.9, the Contractor shall supply, deliver, place and compact granular materials ‘A’ at the following locations to the extent shown on the drawings.

1. Access roads at both Intake and Outlet Areas to the depth as indicated.
2. Platform and construction area at Intake Area.

Granular Materials shall comply with the requirements of OPSS 501, 902, 1010.

All access roads are to be constructed as per cross-sections in the drawings. Sub-base, out of native material, is to be well compacted and ready to receive base course of granular material.

Submit all delivery tickets to the Commissioner. The Contractor shall confirm the top of backfill material elevations to the required elevations for the Commissioner to review prior to the work.

C.9 ASPHALT

Under this item, the Contractor supply, deliver and place the hot mix asphalt on the access roads and platform at Intake and part of main access roads at the Outlet Areas as shown on the drawings. Also included in this item is the all access roads will have ditches in order to control storm water runoff. The water flow in the ditches will be directed towards the existing grounds’ natural drainage – roughly in the area of the new dewatering structure.

Work shall be performed in accordance with OPSS 311, 313 except as modified herein.
Work shall be done by an approved asphalt contractor.

Compaction equipment can be by small roller or the use of vehicle roller. The asphalt material shall be 75 mm HL3 mix.

C.10 TREE PLANTING

Under this item, the Contractor shall plant the trees at both the Intake and Outlet Areas. Also included in this item is the tree planting at the Intake disturbed areas including shrubs and evergreens. Each trees shall be planted in every 100 m² area.

The Contractor shall retain a Professional arborist to review any tree that the Contractor deemed necessary for removal. Trees designated for removal or pruning shall first be approved by the Commissioner before performed by the Contractor using a qualified tree-removal Sub-Contractor. The Contractor shall remove all debris resulting from cutting or pruning.

All work shall be in accordance with OPSS 565 and Canadian Standard for Nursery Stock.

All plant materials are to be balled and burlapped.

No cutting of trees permitted between May 1st to June 15th unless by owner’s permits.

C.11 CULVERTS

C.12 CONCRETE PIPES

Under item 11, the work includes supply, deliver and place pipe culverts under the access roads at both the Intake and Outlet Site Areas as indicated on the drawings.

The size of the culverts varies from 675 mm – 900 mm diameter.

Under item 12, the Contract shall supply, deliver and place concrete pipes from the ground water treatment plant to the HEPC canal.

The size of the concrete pipes varies from 1500 mm – 2000 mm diameter.

All work for these items shall be in accordance with OPSS 421 and OPSS 1820 except as specified herein.

Depth of excavation and placing of culverts and pipes to be governed by the Frost Line – Pipes to be placed below Frost line and to be on granular bedding.

C.13 SANITARY SEWER

This item will be deemed to have included for all works for the connection to the existing sewer at both the Intake and Outlet Site Areas.

All work shall be in accordance with OPSS 406.
C.14 SANITARY SEWER MANHOLE

This item will be deemed to have included for all works for the construction of sanitary sewer manholes at the connection to existing sanitary sewer Line at the Intake Area as well as to Stanley Ave at the Outlet Site Area.

All work shall be in accordance with OPSS407.

C.15 WATERMAIN

This item will be deemed to have included for all works to construct watermain and all associated components for the connection from the Intake Area and the Outlet Site Area to Stanley Avenue to feed offices area.

All work shall be in accordance with OPSS 701.

C.16 LANDSCAPING AT FINAL DISPOSAL AREA

This item will be deemed to have included for all works to landscape the Final Disposal Area at the Outlet Site Area.

All work shall be in accordance with OPSS 570 and 571.

C.17 CONVEYOR BRIDGE

Please refer to the specification item prepared by Strabag.

C.18 NOISE BARRIER

This item will be deemed to have included for all works to design, supply and construction of noise barrier by Durisol Retained Soil System (RSS) or equivalent at the Intake Site Area as shown on the drawings.

Reference:

- OPSS 206, OPSS 501, OPSS 609, OPSS 1350, OPSS 1352
- CSA Z107.9-00 Standard for Certification of Noise Barriers February 2000
- CAN/CSA-S6-00 Canadian Highway Bridge Design Code
- CSA G164-M1981 Hot Dip Galvanizing of Irregularly Shaped Articles
- CSA W 47.1-1983 Certification of Companies for Fusion Welding of Steel Structures
- CSA W 59.1-1982 Welded Steel Construction (Metal-Arc Welding)
- CAN3-A23.2-M77 Method of Test for Concrete
- CAN3-A5-M 1983 Portland Cement/Masonry Cement/Blended Hydraulic Cement

The Contractor shall submit to the Commissioner of all shop drawings for noise barriers at least four (4) weeks prior to the commencement of construction. The shop drawings shall show full
details of noise barrier related items, erection procedures and if applicable, connections to structures. All shop drawings shall bear the seal and signature of an Engineer.

The Contractor shall construct a noise barrier with the following minimum design features:

- The minimum acoustical characteristic of the noise barrier shall be such that the noise barrier is sound absorptive on the construction side.
- Final colour selections will be determined by the Contract Administrator at the point of manufacture from samples prepared by the Manufacturer.

Noise barriers shall be supplied in accordance with OPSS 128. All welds shall conform to CSA W59.1 and CSA W47.1.

Steel posts to which special attachments are welded shall be hot dip galvanized after fabrication according to the requirements of CSA Standard G164-M. Silicone sealant shall be CGE SILPRUF 2000 Series. Concrete in post footings shall be 20 MPa according to the requirements of OPSS 1350.

Where footings are to be installed in earth, concrete for drilled footings shall be cast entirely against undisturbed soil. If other than drilled footings are necessary, the footing shall be formed and the excavation shall be backfilled with granular materials and compacted to at least 95% Proctor. For concrete posts, the concrete working slab below the construction joint in the footing shall be placed a minimum of 4 hours prior to installing the post. Where required, the tops of all footings are to be shaped to provide for full horizontal seating of panels, the remaining surface area is to be sloped away from the post so as to shed water. Stepped footings are to be constructed to suit grade changes.

The concrete in the footings shall be cured for a minimum period of 5 days before the noise panels can be installed.

When rock is encountered within the specified excavation depth for footings in earth, the footing shall be constructed in accordance with the "Footings in Earth" design down to a minimum of 300 mm into the solid rock or 1.5 m below the top of footing grade, whichever is the greater depth.

All excavations into rock shall be backfilled entirely with concrete. The excavation above the top of rock may be formed to the required dimensions and the remainder of the excavation backfilled with granular material.

C.19 TRAIL RELOCATION

This item will be deemed to have included for all works to relocate the existing recreation trail at the Intake Site Area as shown on the drawing. Also included in this item is to connect the relocated portion of recreation trail to the existing trail at both ends. Relocate the recreation trail back to the original position upon the completion of the work.
All work shall be in accordance with OPSS 128.

The new trail layout and material used shall be match the existing recreation trail or to a better condition.

C.20 TOP SOIL AND SODDING

This item will be deemed to have included supply and place topsoil and sodding to the following areas:

1. Reapplying topsoil to the disturbed areas at the Outlet Site Areas including construction offices, materials yard, Final Disposal area, Temporary Stockpile Area for restoration.
2. Applying 150 mm depth topsoil and sodding to the embankment slope behind the East and West Approach Walls at the Intake Areas.
3. Reapplying seeding at all other disturbed Areas.

Also include in this item is to water the placed sod over the warranty period. Any dead sod spots shall be replaced at the Contractor’s own expense.

It is noted that the salt content of the rock from the tunnel may make it difficult to get seed growth.

Work to be done by an approved sodding Contractor.

C.21 Remove and Relocate Existing Watermain

This item will be deemed to have included remove, dispose all material off-site and relocate the existing OPG Watermain at the Outlet Area. All work shall be performed by a qualified Subcontractor.

Two relocation options are proposed:

1. Install approximately 1000 m of new pipe adjacent to the pumping station and bridge the new canal (23 m)
2. Erect a new structure over the existing canal (43 m) adjacent to dewatering structure.

All work shall be in accordance with OPSS 510.

Prior to commencing removal of the existing watermain pipe, the Contractor shall notify the owner of the watermain and also to ensure that the existing watermain has been by-passed, disconnected and/or unoperated.

C.22 REMOVE EXISTING DEWATERING STRUCTURE AT PGS

This work will encompass the removal and disposal all material off-site the existing dewatering structure at the Outlet Area.

The structure will be removed to the bottom of canal bed elevation
All work shall be in accordance with OPSS 510.

C.23 SURFACE PROTECTION FOR GROUND WATER RETENTION POND

This item will be deemed to have included surface protection for the ground water retention pond at the Outlet Area.

Protection can be provided through by the following material:

- Riprap
- Impervious synthetic material
- Clay layer

All work for riprap and impervious synthetic material shall be in accordance with OPSS 511.

C.24 CRUSH STONE

This item will be deemed to have included supply and place crush stone at the following areas:

1. Embankment behind the East and West Approach Walls to the depth as shown on the drawings at the Intake Area.

The crush stone size shall be 150 mm diameter. Stones shall consist of sound, natural, round stone.

No backfill of crush stone shall be placed behind the approach walls until rockfill has been placed up to the desired top level and capped with concrete cover slab.

The depth of the stone shall be placed and layout as shown on the drawings.

C.25 UTILITIES RELOCATION (IF REQUIRED)

This item will be deemed to have included relocate the existing Utilities if required. Prior to the commencement of any work, the Contractor shall stake out and verify all Utilities locations to determine if there are Utilities needed to be relocated at both Intake and Outlet Areas. Upon the completion of the work, the Contractor shall reinstate the Utilities as directed by the Utilities Companies or Agencies.

Any damage to the existing pipe and all associated components / supports that are not specified to be removed shall be repaired by the Contractor to the satisfaction of the Commissioner.

C.26 RESTORATION

The item will be deemed to have included the removal of all temporary installations at both Intake and Outlet Areas (temporary buildings, fences, and all other items deemed removable by OPG), reapplication of topsoil to disturbed areas and to the material berm, providing seeding and cover, and tree planting. The reapplying of topsoil and tree planting is paid under other items elsewhere.
C.27 STRAW BALE

This item will be deemed to have included supply and place straw bale at both sides of the ditch for the following areas:

1. At the intersection of the access roads at the Intake Area and Outlet Area.
2. Along all access roads at every 250 m internal.
3. At the approach of the culverts.

The straw bale is to slow down the flow and to prevent erosion.

6.0 STRUCTURAL WORKS ITEMS

S.1 TEMPORARY DOCK AND ACCESS

Under this item, the Contractor shall provide temporary dock at the Niagara River Shoreline at the location as indicated on the drawings for the transportation and access to the Intake Area Site. The item shall also include other temporary installations/structures for facilitate the removal and deliver material to the intake structure/channel including stairs platform/or construction elevators/tower crane.

Also included in this item is the removal of the temporary dock and installations/structures upon the completion of the Intake Area Work.

All docks must be constructed and designed with engineering certification as to structure durability and effectiveness for the river location. The dock must be completed by a Certified Dock Builder or the owner of the property where the structure is located.

All construction docks must have the plans, specifications, and required calculations submitted and signed by a Professional Engineer experienced in dock design with boat/batch size, wind conditions, and anchorage design equal to or greater than the design being submitted.

American Society of Civil Engineers (ASCE) Manuals and Reports on Engineering Practice No. 50, Planning and Design Guidelines, is a recognized standard and may be used along with the requirements herein. The requirements provided in this specification shall govern over the ASCE No. 50 standard.

All docks shall be constructed with environmentally safe materials.

Structural framing members shall provide corrosion resistance and strength as required by a Professional Engineer.

Anchorage shall be designed with a minimum working load safety factor of 3.0 for cables and 2.0 for chains. Anchorage shall also be galvanized or stainless steel. Anchor design shall be completed with sound engineering practice and the soil properties assumed (if soil testing was not completed) shall be shown on the plan documents. Submerged anchors must be positioned to accommodate low water levels, as not to present a navigational hazard.
S.2  COFFERDAM AND ICE PROTECTION GROYNE

The requirements of OPSS 517 shall apply to this tender item except as modified herein.

Under this item, the Contractor shall design, provide and maintain a cofferdam system including anchors, rip rap and crush stones to the limits at the Intake Area as shown on the drawings. Also included in this item is the removal of Cofferdam including all bracing after the completion of the structure work, care being taken not to disturb or otherwise damage the finished structure.

Cofferdams shall be carried to adequate depths and heights, and be safely design and constructed, and be made as watertight as is necessary for the proper performance of the work which must be done inside them. Cofferdams shall provide sufficient clearance for the construction of forms and shall permit pumping outside the forms.

Cofferdams shall be designed by a Professional Engineer and the plans bearing the Professional Engineer’s stamp and submitted to the Commissioner for approval 10 weeks after the work commencement. These plans shall also contain information as to the design loads and the de-watering and excavation sequence.

S.3  GROUTING

Under this item, the Contractor shall provide a continuous, durable and effective grout zone at the Intake area to the limits as shown on the drawings, appropriate and suitable for the existing subsoil and site conditions, to control all seepage of groundwater and re-grouted where necessary until water ingress is controlled by monitoring.

The Contractor shall be responsible for the design of the multiple grout curtains design. Submit grouting procedures in accordance with the site conditions, working window, and schedule, including the layout of the grout plant and accessory equipment, material storage, fume and dust exhaust and ventilation, access equipment, and other pertinent details, particularly designed to address the space limitation, time restriction, confinement of the tunnel, power supplies, etc. Also submit manufacturers product data, recommended handling and mixing instructions, recommended installation instructions, site conditions which would affect installation procedures, and site conditions which would impose performance limitations.

Monitoring work will be the responsibilities of the Contractor supervised by representatives of the Commissioner.

S.4  SANDBAGS

Under this item, the Contractor shall supply and place cemented sandbags for the precast unit support for the following as shown on the drawings:

1. Leveling the locations of East and West Approach Walls.
2. Leveling the locations of the New Acceleration Wall.
S.5 ROCKFILL

The requirements of OPSS 511 shall apply to this tender item except as modified herein.

Under this item, the Contractor shall supply and place rock for the following as shown on the drawings:

1. Rock fill within the concrete precast units up to the level at the East and West Approach Walls.
2. Rock fill within the concrete precast unit up to the level at the New Acceleration Wall.
3. Rock fill on the overburden slopes for the outlet channel.
4. Rockfill at the ice protection groyne at the Intake Area.

The size of the rock shall be 500 mm diameter. Rocks shall consist of round and natural shape. It shall consist of clean rock fragments and shall be free from organic material. Rockfill shall be reasonably uniformly graded in size up to a maximum of 500 mm and such that not more than 10% by weight shall be less than 150 mm and more than 50% by weight shall consist of particles 300 mm or larger in size.

S.6 REMOVE GUARDRAIL AND POSTS (AS REQUIRED)

Under this item, the Contractor shall remove and salvage the existing guardrail and posts at the Intake Site Area as required to the limit as indicated on the drawings.

Any damage caused to the guardrail and posts by the Contractor’s operation shall be repaired or replaced to the Commissioner’s satisfaction at the Contractor’s expense.

Included in this item is reinstating the guardrail and posts to original details upon the completion of work.

S.7 REMOVE EXISTING ACCELERATION WALL

Under this item, the Contractor shall remove and dispose off site, the acceleration wall system including concrete cap, timber bracing, rock fill and all associated components in stages and sequences to the limit as indicated on the drawings. As part of the removal operation, the Contractor shall supply all necessary equipment and operators to load, haul and dispose of material and debris resulting from the removal work.

The demolition method of the wall shall be undertaken to minimize impact on the operation of the INCW and the environmental impact. Prior to all in-river activities, the Contractor shall coordinate with and obtain approval from Ontario Power Generation.

The Contractor shall ensure that no debris from the removal operations enters into the Niagara River watercourse.
S.8 REMOVE PARTIAL EXISTING PIERS FOR WIDENING

The requirements of OPSS 904, 928 and 929 shall apply to this tender item except as modified herein.

Under this item, the Contractor shall remove and the existing concrete piers including reinforcement to the limit as indicated on the drawings. As part of the removal operation, the Contractor shall supply all necessary equipment and operators to load, haul, and dispose of material and debris off site resulting from the removal work.

Removal method shall be selected to ensure no detriment to the structural integrity of components that will remain during and after the work. Extreme care must be taken not to overbreak the concrete beyond the limits of removal.

No debris and water resulting from removal operations will be permitted to enter the watercourse of the Niagara River unless complying with applicable Municipal by laws and with relevant MOE Standards.

The use of hoe-rams or large impact hydraulic breakers is strictly prohibited. The explosives or implosion procedures is also prohibited.

S.9 CONCRETE – MASS CONCRETE

S.10 CONCRETE – TREMIE CONCRETE

S.11 CONCRETE – CAST-IN-PLACE CONCRETE

Under these items the Contractor shall supply and place concrete for the structure components to the dimensions, shape, thickness, elevations and depths shown on the contract drawings, except for the precast units which will be described and paid under separate items. These components are defined below pertinent to each individual item. The provisions of OPSS 904, 919 and 929 shall apply unless otherwise specified below. All properties of the mix are as describe below, and in accordance with CSA Standard 23.1-00 depending on the exposure of the component.

Under Item S.9, the Contractor shall supply, deposit and compact mass concrete at locations necessary for the construction of the West Approach Slab at the Intake Area (Section C) as shown on the Drawing 2.

Under Item S.10, the Contractor shall supply, deposit tremie concrete at the following locations:

1. Areas necessary for the base of the both East and West Approach Walls construction that are not in dry condition.
2. Areas between the Existing gravity wall and the East Approach Wall.
3. Head and tip of the new Acceleration Wall.

Prior to the placement of mass concrete, the area shall be cleaned of silt and debris. When the mass concrete area cannot be kept water free, procedures for underwater concreting shall be established to include concrete mix design, appropriate admixtures, placement schemes,
inspection plan, and concrete sampling plan to ensure competent concrete is achieved. When the concrete surface has been brought above the water line, regular concrete shall be placed in the dry after all laitance has been removed from the surface of the concrete.

Under Item S.11, the Contractor shall supply, place concrete for the following work as shown on the Drawings:

1. In-fill between the turning area at the West Approach Wall.
2. Concrete cover slab at both East and West Approach Walls, as well as New Acceleration Wall.
3. Extensions at Piers 1 and 2.

The Contractor is also responsible for design of any temporary shoring, and the steel casing with associated strut systems as required for the bridging components and the nose section of the accelerating wall.

Construction activities must not hinder the efficient movement of ice in the vicinity of the INCW.

Work also includes the provision for construction of expansion joints as well as filling, caulking and other accessories shown, sandblasting and roughening of existing concrete surfaces and application of bonding agent where necessary for the proper bonding of new concrete with existing concrete. Compressible filler over existing deck, vent and weep holes at the pier extensions are also part of this item and will not be measured separately. The dowels are not part of this item and will be measured elsewhere.

All concrete work and field testing shall conform to the requirements of CSA Standard A23.1-00 and A23.2-00.

The Contractor shall supply the details of the proposed mix, test results of trial batches of the proposed mix, and bagged samples of the mix constituents for testing by the Region. No concrete shall be placed until the proposed mix has been proven by test results and written authorization to proceed has been issued by the Commissioner.

Calcium chloride shall not be used in the mix under any circumstance. Construction joints other than those shown on the Contract Drawings are not permitted. Construction joints shall be formed as follows:

- Joints shall be neat and properly formed and well bonded
- The exposed face of the concrete at construction joints shall be formed and prepared as shown on the Contract Drawings.
- All faces shall be cleaned prior to placing concrete or cement paste so that all dirt, grease, dust or debris is removed. An excessively rough concrete surface shall not be permitted.
- The surface film laitance and mortar shall be completely removed from the joint face of the hardened concrete to present a clear, sound concrete face that has the aggregate particles exposed.
• After completion of the above preparation, the joint face of the hardened concrete shall be thoroughly wetted (free standing water will not be permitted) and covered with a 10 mm thick brush coating of neat cement paste (1 part cement, 1 part sand and water) immediately before placing fresh concrete.

All dust and loose particles shall be removed from inside the forms using compressed air just prior to placing of concrete. Any surface against which concrete is to be placed shall be pre-wetted just prior to placing the concrete. No standing water shall be permitted in the formwork.

Concrete shall not be placed until all reinforcement and formwork has been inspected by the Commissioner. Access for such inspection shall be provided by the Contractor.

Concrete shall be cured by covering exposed, fresh concrete with at least one layer of wet burlap covered with opaque white plastic sheets for a period of at least seven (7) days. The white filter fabric shall be kept continuously soaked with clean water. Strips of wet burlap shall overlap by at least 150 millimetres. Plastic sheets shall be at least 4 mil thick and shall be of standard commercial quality, free from snags, tears or other flaws in order to provide a tough, pliable moisture barrier. The plastic sheets shall overlap by a minimum of 300 mm and shall be held in place against displacement by wind.

Removal of the forms shall be subject to the following conditions:

• Forms shall not be removed until the concrete has reached a strength of 20 MPa
• Joint faces of hardened and fresh concrete shall be prepared in accordance with the requirements as specified elsewhere in the contract

The Contractor shall remove and dispose of off site all formwork at the completion of the work.

Cold and hot weather concrete shall be in accordance with A23.1-00. No additional payment will be made for cold and hot weather concrete operations.

Formwork and falsework are deemed to be included in the concrete items and will not be measured for payment.

Concrete shall conform to the requirements of A23.1-00 except as noted in this special provision. The Contractor will be responsible for the concrete mix design as specified in CSA Standard A23.1-00 and for providing concrete of the required properties.

When submitting the mix proportions, the Contractor shall specify the source of the coarse and fine aggregate and the manufacturer of the cement.

S.12  CONCRETE – PRECAST CONCRETE

The requirements of OPSS 919 shall apply to this tender item except as modified herein.

Under this item, the Contractor shall fabricate, supply, deliver, store and install precast concrete units to lines and level and construction details at the Intake Area as shown on the drawings. The work includes:

- 4500 mm x 4270 mm precast concrete box units for the East and West Approach Walls including special units as specified on the Drawings.
- 6000 mm x 2000 mm precast concrete box units for the Acceleration Wall.

Shop drawings shall be submitted within 6 weeks from Contract Commencement which shall include detailed calculations, reinforcing steel schedule, concrete mix design and trial mix result, location of concrete plant and unit manufacturing plant, curing information, storage and transportation details. A plan showing the methodology of lifting the precast units into position shall also be submitted. No manufacturing of the units shall commence until approval to proceed is issued by the Commissioner. The Contractor shall allow a review period of 4 weeks by the Commissioner for the initial submission, and 10 working days for subsequent revisions.

The Contractor shall also place smooth bar at corners for docking as shown on the Contract Drawings. Other features such as grouting, joint fillers, and other as shown on the drawings, shall be deemed to be included in the lump sum bids for this item.

Before the work commencement of the Acceleration Wall and Approach Walls construction, the Contractor shall carry out field survey including hydrographic surveys.

for the alignment of the walls for every 5 m interval to verify all dimensions and position for the placement of Walls.

S.13  REINFORCEMENT – UNCOATED REINFORCEMENT

The requirements of OPSS 905 shall apply to this tender item except as modified herein.

Under this item, the Contractor shall supply and place all uncoated reinforcing steel including dowels as shown on the Contract drawings. Reinforcement shall be Grade 400 unless otherwise specified.

All reinforcing steel shall be conform to CAN/CSA Standard G30.18M92 (R1998).
The Contractor shall be responsible for the preparation of the bar schedule and shall submit the bar schedule for approval to the Commissioner at least 14 days prior to ordering the coated reinforcing steel. Fabrication shall not commence until the Contractor has received the Commissioner’s written approval.

S.14 DOWELS INTO CONCRETE

This item specifically refers to the provision and installation of uncoated dowels, for the construction of the pier extensions, approach walls and acceleration wall at the Intake Areas.

Included in the construction of the dowels are the drilling of correct diameter holes into existing concrete mass to the depths shown, supply and placement of approved epoxy grouts, and the supply and installation of steel dowels.

Reinforcing steel used for the dowels are deemed to be included in this items and will not be measured under reinforcing steel items. Additionally, no separate payment will be made for the drilling and grouting for these dowels.

Prior to the construction the Contractor shall submit for the Commissioner’s approval literature and samples of the proposed epoxy grout to be used for the anchoring of the dowels. The materials shall be one selected from the list of Designated Source of Materials of the MTO. All work in this item shall meet the requirements of OPSS No. 904 and 905. All reinforcing steel shall be conform to CAN/CSA Standard G30.18M92 (R1998).

Dowels shall be free from dirt, oil or paint, and shall be installed according to the provisions of OPSS 904.07.10. Drilling though existing reinforcing steel for the installation of dowels is not permitted. Positions of dowels may be slightly shifted to adjust for physical difficulties.

All dowels shall be capable of developing the full yield strength of the steel after installation and cured. The Commissioner will carry out pull-out test to confirm the capacity of each dowel. All dowels which fail to meet the requirement shall be reinstalled at the Contractor’s expenses.

S.15 DOWELS INTO ROCK

This item specifically refers to the provision and installation of rock reinforcing dowels, for the construction of the pier extensions at the Intake Areas as shown on the Drawings.

Included in the construction of the dowels are the coring of correct diameter holes into existing concrete mass to the depths shown, supply and placement of approved epoxy grouts, and the supply and installation of steel dowels.

All dowels in rock shall be installed using either cementitious or resin-type grout with procedures recommended by the manufacturer.

Reinforcing steel (Dywidag bars) used for the dowels are deemed to be included in this item and will not be measured under reinforcing steel items. Additionally, no separate payment will be made for the coring and grouting for these dowels.
Prior to the construction the Contractor shall submit for the Commissioner’s approval literature and samples of the proposed epoxy grout to be used for the anchoring of the dowels. The materials shall be one selected from the list of Designated Source of Materials of the MTO. All work in this item shall meet the requirements of OPSS No. 904 and 905. All reinforcing steel shall be conform to CAN/CSA Standard G30.18M92 (R1998).

Protect rock reinforcing dowels at all times from damage and corrosion. Corrosion, pitting or damage to the dowel may be cause for rejection. Damage includes, but is not limited to, abrasions, cuts, nicks, welds, and weld splatter. Dowels shall be free from dirt, oil or paint, and shall be installed according to the provisions of OPSS 904.07.10. Additionally, all rock reinforcing dowels, accessories, and hardware shall have an approved corrosion protection coating. Core holes to the diameter and depth recommended by the manufacturer. Unless otherwise directed, align core holes normal to the rock face or as specified. Positions of dowels may be slightly shifted to adjust for physical difficulties.

All dowels shall be capable of developing the full yield strength of the steel after installation and cured. The Commissioner will carry out pull-out test to confirm the capacity of each dowel. All dowels which fail to meet the requirement shall be reinstalled at the Contractor’s expenses.

S.16 REINFORCEMENT – MECHANICAL COUPLERS

Under this item, the Contractor shall supply and install mechanical couplers to connect reinforcing steel at the West Approach Wall (Section C) as well as at the Pier extension for the rock dowels as indicated on the contract drawings. Mechanical couplers required arising from the Contractor’s chosen method of construction or fabrication mistakes shall be borne by the Contractor. All work in this item shall meet the requirements of OPSS No. 905. All reinforcing steel shall be conform to CAN/CSA Standard G30.18M92 (R1998).

All mechanical couplers shall be of approved type by the Ministry of Transportation and named in the list of “Designated Source of Materials” and shall be appropriate for the type of construction encountered in this project.

S.17 SEALING FOR DOWNSTREAM CLOSURE

Under this item, the Contractor shall supply, install and maintain the sealing system at the downstream closure between Pier 1 and Pier 2 at the intake area during the construction as shown on the Drawings. This item also includes removal of the sealing system upon the completion of the work with the approval of the Commissioner.

S.18 GEOTEXTILE

Under this item, the Contractor shall supply and place geotextile behind the East and West Approach Walls at the Intake Location as well as on the overburden slopes for the outlet channel as shown on the Drawings. Placement of the geotextile shall be limited to the length as shown on the Section C of Drawing 1. This item also includes surface preparation for existing ground necessary for the proper installation of the geotextile.
Geotextile shall be Class 1, non-woven geotextile FOS 75-150 µm or approved equal. All work in this item shall meet the requirements of OPSS No. 1860.

S.19 MISCELLANEOUS STRUCTURAL STEEL

Under this item, the Contractor shall fabricate, deliver, and install miscellaneous structural steel including, but not limited to:

1. Steel nosing at the Pier 2.
2. Steel cover at the Piers 1 and 2.
3. Steel casing at end panel of new acceleration wall.
4. Access opening floor door with including ladder and safety post at Piers 1 and 2.

The work shall be done using structural steel Grade 400 and in accordance with the requirement of OPSS 906.

All steel shall be atmosphere corrosion resistant weldable steel, CSA G40.21-350A and hot-dip galvanizing shall be to CSA G164-92, OPSS 911 and double-dipped. A company certified in Division 1 or Division 2 of CSA Standard W47.1-92 shall complete all welding. All field welds to galvanized steel shall be painted with two coats of zinc rich paint.

S.20 ARMORING BOULDERS

The requirements of OPSS 511 shall apply to this tender item except as modified herein.

Under this item, the Contractor shall supply and place armouring boulders at the ice protection/deflection groyne as shown on the drawings.

The size of the boulder shall be 2 m x 2 m x 1m. Boulders shall consist of round and natural shape. It shall consists of clean rock fragments and shall be free from organic material.

S.21 SHOTCRETING

Under this item, the Contractor shall provide and place shotcreting at the Outlet area to stabilize the rock above the elevation 165.5.

Shotcrete shall be produced by wet mix process achieving a minimum compressive strength of 18 MPa in 7 days and 30MPa in 28 days. Shotcrete will be accepted based on 28-days strength. The Contractor shall submit a proposal for expediting the work. The contract’s proposal shall detail methods to ensure that the minimum required 28-days strength is attained.

Provide equipment capable of delivering the premixed material accurately, uniformly and continuously through the delivery hose. Follow recommendations of the equipment manufacturer on they type and size of nozzle to be used and on cleaning, inspection and maintenance of the equipment. Ready mixed shorcrete shall be delivered in transit mixers.

Provide undisturbed gun finish of shotcrete as applied from nozzle without hand finishing. A clean area at base of each lift is required to ensure good bonding interface between lifts.
After each stage of cut, in anticipation of shotcreting, clean surfaces of all loose material, mud, rebound from previously placed shotcrete and other foreign matter that will prevent bonding of shotcrete shall be removed from the cut surface and dampen surface before shotcreting.

The shotcrete shall be applied from the bottom up to prevent accumulation of rebound shotcrete deposited on the surface still to be covered. Shotcrete shall emerge from the nozzle in a steady uninterrupted flow.

1. Introduction

1.1 Subject of Technical Specification
This Technical Specification (TS) shall define the requirements for the execution and commissioning of the steel ribs forming part of the support measures for the tunnel excavated at the Niagara Tunnel Facility Project.

1.2 Range of Technical Specification Application
This TS is a bid and contract document used in the execution and commissioning of the works referred to in Item 1.1.

The provisions contained in this Specification refer to the working methods to be adopted for the:

a) delivery of steel ribs incl. all the components and the entire equipment to the site
b) installation and fixing of steel ribs
c) quality control for material and workmanship.

The Scope of Work is defined for the crown and the sidewalls of the main tunnel during the excavation and support period.

1.3 Definitions
The basic definitions given in this TS are in conformity with the relevant standards in force.

1.3.1 ROLLED STEEL RIBS
Steel ribs shall be installed as a means of immediate support at the working face over the entire length of the last excavation advance to prevent spalling, to improve the load distribution and to enhance the effectiveness of the rock dowels.

The steel ribs are produced of rolled steel and delivered in segments. They will be assembled on site to the complete arch required. Each steel rib segment has welded steel plates at both its ends for connection with others. The segments are prefabricated.

1.3.2 CONNECTIONS
The steel rib segments will be connected on site to their complete form. The connection will be done by linking the steel plates at the ends of the segments with screws or bolts. The type of connection, hinge or stiff, has to be arranged in line with the design. Bolts have to be secured against dropout by split pins.

Hinge connections shall be capable of transferring the full section axial compressive forces and shear forces. The adequacy of connections may be demonstrated by calculation or by load test.
Technical Specification  
Steel Ribs

Stiff connections shall be capable of resisting the full sectional bending moments, axial forces (tension and compression) and shear forces. The adequacy of these and other more complex connections shall be proven by testing.

The connections shall be designed to allow complete covering with shotcrete or surrounding by concrete, so that no voided areas are created behind the connections.

1.3.3 WELDING

Welding is used to connect the steel segments. The welded segments shall be of the same steel type and quality. The welded connections shall satisfy the same requirements as the original steel profiles. All welding works shall be carried out in accordance with the corresponding standards in force.

Welding on site, in the tunnel should be avoided due to the danger of fire.

1.3.4 FIXING

Steel rib supports shall be fixed to the excavation surface with rock dowels, or shall be supported by shim wedges on sound undisturbed rock or soil base. Timber wedges or blocks shall not be permanently incorporated in the lining.

Adjacent ribs shall be tied and braced as necessary for stability.

1 General Work Requirements

The Contractor shall be responsible for the quality of material and workmanship and for their conformity with the Design Documentation, other corresponding Specifications and Method Statements and the Engineer's instructions.

The Contractor shall provide his personnel with the equipment necessary in accordance with the Specification and shall grant them access to the works to carry out their work in a safe and proper way.

2 Materials

Steel ribs are made of rolled steel according to CSA G 40.20 and G 40.21. Rolled steel ribs and attachments thereto, ties, spreaders and collar braces shall consist of weldable structural steel and shall have a minimum characteristic strength of 240 MPa.

The steel ribs shall be cold worked to the required radii. The rolled profiles shall comply with the required dimensions and masses shown on the drawings and shall be within a tolerance of 2.5 % of the mass per unit length and within a tolerance of + 3 mm and - 1 mm of the required depth. The shape of the rib shall conform to the true design templates at the ends of the segments, while intermediate points may depart by up to 10 mm from the true templates, provided that no point shall depart more than 3 mm from a template section 1 m long.
The steel ribs shall be free of cracks and flaws and shall be well finished, without rough or jagged edges or other imperfections. The ends shall be clean, smooth and, where necessary, dressed before despatch.

The blocking shall be hardwood unless otherwise specified. Foot plates shall have adequate bearing capacity.

3. **Equipment**

The works may be performed using any type of equipment approved by the Engineer.

The entire equipment must have a valid quality control certificate and is to be inspected within regular inspection periods.

4. **Transport**

All components of the steel ribs shall be transported by suitable means of transport and in accordance with industrial safety and road traffic regulations to avoid any damage.

5. **Workmanship**

The Contractor shall present an organisational chart and time schedule of the works to the Engineer for approval. These documents shall give due consideration to all conditions accompanying the execution of the works.

The type, size and spacing of the rolled steel ribs shall be as shown on the Drawings. The steel ribs shall be erected within the specified tolerances and shall be firmly set off the rock or the shotcrete by spacers arranged around the periphery of the rib as shown on the Drawings.

Fully detailed fabrication drawings and specifications for all steel rib components shall be prepared prior to any manufacturing. The manufacturing process shall be in accordance with these drawings and specifications.

At the time the steel ribs are encased in shotcrete or concrete, they shall be free of mud, oil, paint, concrete retarders, loose rust, loose mill scale, grease or any other substance which could adversely affect the steel or concrete chemically, or reduce the bond.

Rust can be tolerated subject to approval by the Engineer.

Each rib set, when assembled with the connections fully and tightly bolted, shall lie within ± 25 mm of a true plane. The ribs shall be erected within ± 150 mm of the positions shown on the drawings unless otherwise approved by the Engineer and shall not deviate by more than ± 50 mm from the profiles shown on the drawings.
6. **Quality Control**

All components must have a valid quality certificate and a valid permission for the intended use.

To achieve a sufficient quality of the installed product, suitability tests and work tests have to be carried out for the individual components as well as for the installed products.

The strength of the steel ribs shall be demonstrated by calculations or by load tests. Where tests are necessary, they shall be performed in accordance with the test procedures approved by the Engineer.

Tests shall be in conformity with the following requirements:

(a) The test piece shall consist of a straight steel rib with a length of 4.5 m restrained by a pinned support at one end, and a pinned roller support at the other end.

(b) A uniformly distributed vertical loading of 5.0 kN/m shall be applied over the entire length of the girder. At the same time a horizontal compressive load of 125 kN shall be applied at the roller support. The rib shall not collapse under the combined loading.

Where the strength of the ribs is demonstrated by calculation, an ultimate limit state check shall be carried out using the loads specified in Subchapter 3 above with a partial safety factor for loads of 1.0. The partial safety factor for material strength shall be 1.15.

7. **Units**

The quantity survey unit of the steel ribs shall be ton. The numbers and types of the steel ribs depend on the individual excavation and the support type executed. The respective numbers and types are documented in the corresponding drawings.

8. **Acceptance**

8.1 **Conformity of Work with Design and Technical Specification**

The works shall be carried out in accordance with the design, the Technical Specification(s) and the written instructions of the Engineer.

8.2 **Acceptance of Works To be Removed or Covered**

8.2.1 **DOCUMENTS AND DATA**

The acceptance of works which are to be removed or covered shall be based upon:

- a written statement by the Engineer entered into the Site Book that the works have been executed in accordance with the design and the Technical Specification,

- other written statements by the Engineer commenting on the execution of the works.
8.2.2 SCOPE OF WORKS

The scope of works to be removed or covered shall be determined by written statements of the Engineer and by other documents confirmed by the Engineer.

9. Applicable Regulations

9.1 Standards ....................................................................................................... 5
1. **Introduction**

1.1 **Subject of Technical Specification**

This Technical Specification (TS) shall define the requirements for the execution and commissioning of reinforcement, wire mesh and reinforcement bars forming part of the support measures for the Diversion Tunnel, as well as for the pits of the intake and outlet structures at the Niagara Tunnel Facility Project.

1.2 **Range of Technical Specification Application**

This TS is a bid and contract document used for the execution and commissioning of the works referred to in Item 1.1.

The provisions contained in this Specification refer to the working methods to be adopted for:

a) delivery of reinforcement incl. all components and entire equipment to the site
b) installation and fixing of wire mesh and reinforcement bars,
c) quality control for material and workmanship.

The Scope of Work is defined for the crown and the sidewalls of the main tunnel during the excavation and support period.

1.3 **Definitions**

The basic definitions given in this TS are in conformity with the relevant standards in force.

1.3.1 **WIRE MESH**

The wire mesh is used for:

- reinforcement required in the shotcrete lining
- first protection against breakout (in combination with steel ribs or rock dowels)
- improvement of shotcrete's composite behaviour

The wire mesh shall have a square pitch pattern of 100 mm in both directions. The wire diameter shall range between 5 mm and 8 mm. Standard sizes shall be preferred. If the required reinforcement area can not be covered with standard sizes, the above mentioned criteria have to be considered. Twin bars in the bearing direction are admissible.

1.3.2 **REINFORCEMENT BARS**

Reinforcement bars are generally used to connect the reinforcement of the individual excavation stages (starter bars). Adequate measures have to be taken to ensure that the bars will be protected against damage during the excavation of the next phase.
Bars can also be added to the wire mesh in case the required reinforcement exceeds the wire mesh dimensions locally.

1.4 General Work Requirements

The Contractor shall be responsible for the quality of material and workmanship and for their conformity with the Design Documentation, other corresponding Specifications and Method Statements and the Engineer's instructions.

The Contractor shall provide his personnel with the equipment necessary in accordance with the Specification and shall grant them access to the works to carry out their work in a safe and proper way.

2. Materials

The wire mesh should be of high-tensile steel quality with a characteristic strength of 500 MPa and a yield strength of 550 MPa. The steel should be classified as weldable.

The reinforcement bars should be of high-tensile steel quality with a characteristic strength of 500 MPa and a yield strength of 550 MPa. The steel should be classified as weldable.

If lower quality steel is used (e.g. characteristic strength = 420 MPa, yield strength = 500 MPa), the conversion of the required reinforcement shall be made with the ratio of the characteristic strength.

3. Equipment

The works may be performed using any type of equipment approved by the Engineer.

The entire equipment must have a valid quality control certificate and is to be inspected within regular inspection periods.

4. Transport

All components of the reinforcement shall be transported by suitable means of transport and in accordance with industrial safety and road traffic regulations to avoid any damage.

5. Workmanship

The Contractor shall present an organisational chart and time schedule of the works to the Engineer for approval. These documents shall give due consideration to all conditions accompanying the execution of the works.
The wire mesh shall be installed in such a way that it follows the contours of the excavated and sealed excavation surface as closely as possible. The spacing between the excavation surface and the wire mesh should not exceed 10 cm.

The wire mesh shall be placed firmly, shall securely be held in position and shall be cleaned from rebound before shotcreting. It shall be fastened with short bolts, reinforcement bars, length approx. 30 cm, which are drilled and fixed in the surrounding rock mass, or supported by installed steel ribs.

Larger overbreak shall be filled with shotcrete before wire mesh is installed.

The wire mesh shall be installed in the longest practical length. Adjoining pieces shall be overlapping:

Radial overlap: minimum 30 cm.

Longitudinal overlap: minimum 15 cm.

The steel bars, used as connection bars between the heading and bench reinforcement shall be covered and protected against damage in the case of bench excavation.

6. Quality Control

All components must have a valid quality certificate and a valid permission for the intended use.

The correct construction, in accordance with the corresponding drawings, specifications and method statements shall be checked by visual inspection.

7. Units

The quantity survey unit of the reinforcement (wire mesh and steel bars) shall be ton (weight).

8. Acceptance

8.1 Conformity of Work with Design and Technical Specification

The works shall be carried out in accordance with the design, the Technical Specification(s) and the written instructions of the Engineer.

8.2 Acceptance of Works To Be Removed or Covered

8.2.1 DOCUMENTS AND DATA

The acceptance of works which are to be removed or covered shall be based upon:
• a written statement by the Engineer entered into the Site Book that the works have been executed in accordance with the design and the Technical Specification,
• other written statements by the Engineer commenting on the execution of the works.

8.2.2 SCOPE OF WORKS

The scope of works to be removed or covered shall be determined by written statements of the Engineer and by other documents confirmed by the Engineer.

9. Applicable Regulations

9.1 Standards

Canadian Standards
CSA A23.1-94 Concrete materials and methods of concrete constructions

German Standards
DIN 1045 (EC 2) Concrete structures: design and construction

***
1. Introduction

1.1 Subject of Technical Specification
This Technical Specification (TS) shall define the requirements for the execution and commissioning of the rock dowels forming part of the support measures for the tunnel excavation and other cavities or pits at the Niagara Tunnel Facility Project.

1.2 Range of Technical Specification Application
This TS is a bid and contract document used for the execution and commissioning of the works referred to in Item 1.1.

The provisions contained in this Specification refer to the working methods to be adopted for the:

a) delivery of rock dowels with all components and equipment to the site
b) installation of rock dowels,
c) quality control for workmanship and material.

The Scope of Work is defined for the crown and the sidewalls of the excavation of the main tunnel and for the excavation of pits for the corresponding adjacent structures (e. g. intake, outlet).

1.3 Definitions
The basic definitions given in this TS are in conformity with the relevant standards in force.

1.3.1 ROCK DOWELS SWELLEX TYPE OR SIMILAR
This type of rock dowel is manufactured from a mechanically reshaped steel tube. Bushings are pressed onto the ends, which are sealed through welding. The lower bushing has a flange to hold a face plate in place. High-pressure water (300 bar) is injected into the steel tube through a hole in the lower bushing. This causes the steel tube to expand and to adjust to the irregularities of the drilled hole. A 200 mm long sleeve tube made of steel prevents the dowel from swelling at the drillhole mount. As the swelling process occurs, the lower part of the steel tube shortens, pulling the face plate firmly against the rock face. The water pressure is released after installation and the water is allowed to drain out of the expanded steel tube. The drillhole diameter has to be adjusted to suit the size of the rock dowel.

1.3.2 ROCK DOWELS SN TYPE – RESIN OR RESIN GROUTED
This type of rock dowel is an untensioned rod inserted into a drilled hole and grouted along its entire length using cement grout and resin capsules or resin capsules exclusive. The rock dowel consists of a high-yield steel deformed ribbed bar with cut or rolled threads at one end, a face plate, shim plates and a nut.
1.3.3 ROCK DOWELS SELF-DRILLING TYPE - GROUTED

This type of dowel is equipped with a drill bit on one end and is made from high tensile steel tubes. The rock dowel is directly drilled in the borehole and afterwards grouted "under pressure" through the tube to the end of the rod and on the outside back through the borehole. These dowels shall be used in very weak soil and rock formations. If the required dowel length is longer than the diameter of the tunnel, couplings shall be used to adjust the length of the dowel.

1.3.4 GENERAL WORK REQUIREMENTS

The Contractor shall be responsible for the quality of material and workmanship and for their conformity with the Design Documentation, other corresponding Specifications and Method Statements and the Engineer's instructions.

The Contractor shall provide his personnel with the equipment necessary in accordance with the Specification and shall grant them access to the works to carry out their work in a safe and proper way.

2. Materials

1. A detailed statement of the types and sources of manufacture of the rock dowels proposed for use in the works, shall be prepared.

2. The characteristic strength / yield strength of the steel should not be less than 420 / 500 MPa. The steel plates, washers and nuts should have the corresponding quality and shall comply with the requirements of the corresponding standards.

3. The characteristic load F of rock dowels is defined with the bearing capacity of the dowel at failure. The safety against failure should be 1.3.

   The design load is defined with:
   100 kN for dowels with a length up to 4 m (type I)
   200 kN for dowels with a length of more then 4 m (type II)

4. For rock dowels of the SN type, the minimum steel cross-section should not be smaller than:
   250 mm² for rock dowels - type I
   450 mm² for rock dowels - type II

5. Face plates shall be of dished shape in steel and shall have a hemispherical seating and a centralized slot to suit the dimensions of the different rock dowels. The dimensions of the face plates shall be (length / thickness)
   Ø 60 / 6 [mm] for rock dowels of the Swellex type
   100 / 100 / 6 [mm] for rock dowels of the SN type (type I)
   150 / 150 / 8 [mm] for rock dowels of the SN type (type II)

6. Cement for cement grout shall be ordinary Portland or rapid hardening Portland cement.
7. Aggregates for cement grout shall contain high-quality quartz sand with a particle size of up to 1 mm.

8. Cement grout shall achieve such a characteristic strength that the dowel will be able to bear 40% of its capacity after 6 h and 100% of its capacity after 12 h.

9. Admixtures shall be plasticizers and expanding agents. The admixtures used shall have no detrimental effect on the performance of the rock dowels. Admixtures containing chlorides shall not be used.

10. Resin capsules shall be of the fast setting type conforming to the manufacturer's specification and compatible with the cement grout, in case they are used as a hybrid doweling system.

3. Equipment

The works may be performed using any type of equipment approved by the Engineer.

The entire equipment must have a valid quality control certificate and is to be inspected within regular inspection periods.

The mortar pump must be capable of producing a minimum pressure of 3 MPa at its mouth.

4. Transport

All components of the dowels shall be transported by suitable means of transport and in accordance with industrial safety and road traffic regulations to avoid any damage.

5. Workmanship

The Contractor shall present an organisation chart and time schedule of the works to the Engineer for approval. These documents shall give due consideration to all conditions accompanying the execution of the works.

In addition, further issues have to be considered:

1) The rock dowels shall be installed in the positions, the sequence and at the spacing shown on the drawings. The exact locations of the dowels shall be adapted to suit the prevailing geological conditions. When necessary to ensure the safety of the works, rock dowels shall be installed at and immediately behind the excavation face.

2) The holes for the installation of the rock dowels shall be drilled into the ground to the lengths indicated or stated on the drawings and shall be inclined in such a way that the dowels are generally installed perpendicular to the designed surface of the excavation. The holes shall be drilled with an accuracy of ± 15°.
3) The holes shall be drilled using sharp bits to produce straight holes of the required length. On completion of each drillhole and prior to the installation of each dowel, the drillholes shall be cleaned removing debris. In clay formations, sensitive to water, flushing the drillhole with water shall be avoided (auger drilling technique). The drillhole diameter shall be within the range recommended by the rock dowel manufacturer to match the particular rock dowel diameter and any couplers required for extending the dowel. It shall be not less than 2 times the rod diameter.

4) The installation shall be carried out in accordance with the rock dowel manufacturer’s recommendations, generally adopting the following procedure:
   (a) A regular surface, normal to the drillhole, shall be provided to seat the face plate. Some preparation of the ground or shotcrete surface in the vicinity of the drillhole / dowel location may be necessary, involving trimming local surface irregularities or forming pads of quick-setting mortar. Where mortar pads are required they shall be larger than the face plates and the edges shall be chamfered at 45°.
   (b) The dowels shall be installed in accordance with the drawings and site instructions given by the Engineer. 24 hours after installation, nuts shall be screwed tightly so that the face plates are held firmly against the surface using hand wrenches.
   (c) With cement grouted dowels, the grouting material shall be injected starting from the furthest end of the drilled hole such that the dowel rod is completely encased in grout. Tremie and vent pipes shall be provided as necessary for grouting and the open ends of holes shall be sealed to prevent grout loss. Any grout on the exposed threads of the dowels shall be cleaned off.
   (d) The cement mortar grout shall be chosen to be of such consistency that it does not flow out of the borehole even if the borehole is vertical upward. Dowels installed in overhead positions shall be supported where necessary until the grout has set.

6. Quality Control

All components must have a valid quality certificate and a valid permission for the intended use. To achieve a sufficient quality of the installed product, suitability tests and work tests have to be carried out for the individual components as well as for the installed products.

6.1 Testing of Components

6.1.1 TESTING OF CEMENT GROUT

Sets of six cubes of cement grout shall be taken once every month when installation of grouted rock dowels is in progress. Sampling, preparation, curing and testing shall be in accordance with EN 196-1.

Half of the cubes shall be tested at 1 day and the remainder at 28 days. The average compressive strength determined from any group of four tests shall be at least the specified characteristic strength.
The strength determined from any single test result shall not be less than the specified characteristic strength minus:

1 N/mm² for cement grout tested after 1 day
3 N/mm² for cement grout tested after 28 days

6.1.2 TESTING OF THREADED BARS
Tensile tests shall be carried out on a number of steel dowel bars, covering the threaded length of each batch of bars. At least three bars in every 1000 shall be tested to destruction. Tests may be carried out at the manufacturer's works or on site. Test certificates shall be provided.

6.2 Trials and Testing of Dowels

6.2.1 SUITABILITY TESTS
1. Prior to the installation of the dowels, 10 trial rock dowels of each type of dowel to be used in the works shall be installed and tested. 5 of the trial Swellex-type rock dowels shall be tested immediately at 60% of the characteristic load and 5 of the resin-grouted rock dowels shall be tested after 1 hour. The remaining dowels shall be tested at the characteristic load between 3 and 21 days after installation.

2. Trial dowels shall be installed in similar rock conditions to those which are likely to be encountered during installation in the works and shall be in accordance with this Specification.

3. Additional rock dowel tests shall be carried out if the procedures adopted for the installation of the dowels do not match those adopted for the preconstruction suitability tests. If the test results on dowels used in the works when compared with the results of the original trial tests show inadequacies in the load-carrying capacity, a detailed investigation and further tests to identify and rectify the inadequacies shall be carried out.

6.2.2 WORKS TESTS
1. Five percent of the installed dowels shall be tested to the characteristic load between 3 and 21 days after installation. The quality control criteria are met, if the design load is reached within a maximum deformation (tension) of about 10 mm.

The proportion of the dowels tested to characteristic load may be varied, if consistent test results were obtained for the previous 50 dowels tested, subject to approval by the Engineer.

2. The in-situ tests shall in general be carried out by pull-out tests or in accordance with a method for determining the strength of a rock dowel proposed by the Contractor.

3. The rock dowels shall be deemed to be acceptable provided the working load is sustained for at least 10 minutes.
6.2.3 EVALUATION

Records shall be kept for each dowel tested in accordance with the procedures agreed with the Engineer, and copies of all records shall be maintained on site after installation of the dowel or completion of the testing, as appropriate.

The number of dowels which do not reach the quality criteria is extrapolated to the total number of the testing cycle. The Engineer together with the Contractor will have to decide on an additional installation of dowels or adequate substitute measures.

7. Units

The quantity survey unit of the dowels shall be piece. The numbers and types of dowels depend on the individual excavation and the support type executed. The respective numbers and types are documented in the corresponding drawings.

8. Acceptance

8.1 Conformity of Work with Design and Technical Specification

The works shall be carried out in accordance with the design, the Technical Specification(s) and the written instructions of the Engineer.

8.2 Acceptance of Works To Be Removed or Covered

8.2.1 DOCUMENTS AND DATA

The acceptance of works which are to be removed or covered shall be based upon:

- a written statement by the Engineer entered into the Site Book that the works have been executed in accordance with the design and the Technical Specification(s),
- other written statements by the Engineer commenting on the execution of the works.

1. **Introduction**

1.1 **Subject of Technical Specification**
This Technical Specification (TS) shall define the requirements for the execution and commissioning of the shotcrete lining forming part of the support measures for the excavated tunnel and other cavities or pits at the Niagara Tunnel Facility Project.

1.2 **Range of Technical Specification Application**
This TS is a bid and contract document used for the execution and commissioning of the works referred to in Item 1.1.

The provisions contained in this Specification refer to the working methods to be adopted for the:

a) delivery of all the components and the entire equipment to the site
b) execution of shotcrete works
c) quality control for material and workmanship.

The Scope of Work is defined for the crown, the sidewalls and the invert of the excavated main tunnel and for the excavation and support of pits for the corresponding adjacent structures (e. g. intake, outlet).

1.3 **Definitions**
The basic definitions given in this TS are in conformity with the relevant standards in force. Special definitions shall be presented below.

1.3.1 **SHOTCRETE**
Shotcrete is a mixture of cement, aggregate and water, which may contain admixtures, projected from a nozzle into place to produce a dense homogeneous mass.

1.3.2 **DRY METHOD**
A method of producing shotcrete, in which a mixture of cement, aggregates, and admixtures (if required) is weight batched, thoroughly mixed in a dry condition and fed into a purpose-made machine in which the mixture is pressurised, metered into a dry air stream and conveyed through hoses or pipes to a nozzle, where water as a spray is introduced into the mix which is projected without interruption into place.

1.3.3 **WET METHOD**
A method of producing shotcrete, in which cement and aggregates are weight batched and mixed with water at the shotcreting location or in mixer trucks prior to being pumped through a
pipeline to a nozzle where air, and admixtures are injected - if necessary - and the mix is projected into place without interruption.

1.3.4 LAYER
A term used for a discrete thickness of shotcrete built up from a number of passes of the nozzle and allowed to set.

1.3.5 REBOUND
A term used for all the material having passed through the nozzle which does not adhere to the surface on which shotcrete is being applied.

1.3.6 BASE CONCRETE
A term used for all the concrete of a design intended for use in shotcrete, but produced without admixtures.

1.3.7 CEMENT AND LATENT HYDRAULIC BINDERS (LHB)
Hydraulic cement is an active hydraulic binder formed by grinding clinker.
Latent hydraulic binders are added to the cement in two forms:
- as hydraulic binder, manufactured by a controlled process in which Portland cement clinker or Portland cement is combined in specified proportions with a latent hydraulic binder consisting of pulverized fuel ash (pfa).
- as hydraulic binder, manufactured in the concrete mixer by combining Portland cement with a latent hydraulic binder consisting of pulverized fuel ash and/or silica fume.

1.3.8 ADMIXTURES
A term used for materials which are added to the base concrete such as accelerators, plasticizers and retarders.

1.4 General Work Requirements
The Contractor shall be responsible for quality of material and workmanship and for their conformity with the Design Documentation, other corresponding Specifications and Method Statements and the Engineer’s instructions.

The Contractor shall provide his personnel with the equipment necessary in accordance with the Specification and shall grant them access to the works to carry out their work in a safe and proper way.
2. Materials

2.1 Water
The water shall be clean and free of harmful matter in such quantities as would affect the properties of shotcrete in the plastic or hardened state.

2.2 Cement
It is of particular importance to use cement of uniform chemical composition and uniform fineness. The required characteristic values shall be approved by the Engineer. For the entire cement delivered, the manufacturer shall make the cement analyses and the standard test results available. Quality control measures are detailed below.
The cement shall comply with the following requirements:
- Only cement with a suitable fineness of grinding shall be used.
- Chrome content (Cr²⁺): not more than 2 mg/kg.
- Fineness: not less than 340 m²/kg.
- Bleeding: not more than 20 cm³.

2.3 Aggregates
Aggregates shall comply with the following requirements:
The maximum particle size shall not exceed 11 mm.
Single size aggregates shall be combined in the proportions determined during the site trials.
Fine and coarse aggregates shall be clean. The grading shall remain within the acceptable range and wherever possible within the desired range according to the grading curve - Figure 1
- The coarse fraction of the aggregate shall not exhibit excessive fragmentation during delivery. The percentage of particles smaller than 0.075 m shall not exceed 3%.
- Frozen aggregates shall not be used.
- For the dry method, at the time of mixing, the moisture content of the combined aggregates shall not exceed the saturated surface dry value by more than 5% unless otherwise approved by the Engineer.
2.4 Admixtures

2.4.1 GENERAL

The Engineer shall consider any potential for admixtures contaminating groundwater by giving or withholding approval for their use.

Retarding and plasticizing admixtures shall comply with ENV 206 or the corresponding Canadian Standards.

The compatibility of all admixtures with each other and with all other shotcrete constituents shall be verified during the site trials (reference is made to Subchapter 5.1.3, Shotcreting Trials)

2.4.2 ACCELERATORS

Only the minimum quantity of accelerators necessary shall be permitted in normal shotcreting operations, and this quantity shall be determined by trials as specified herein.

Testing of accelerators, with regard to setting time and strength decrease at a later age (28 days), shall take place in due time before commencement of shotcreting. For this purpose the method specified in Subchapter 6.2.2, Testing of Accelerators shall be used. All components - unless otherwise specified in the test method - shall be fully representative of those which will be used in the works.

If the sulphate (SO₄) content of the groundwater is more than 600 mg/l, the water-soluble aluminate in the accelerator shall not be greater than 0.6 % by weight of the cement content.
The accelerators delivered to the site shall be tested in accordance with this Specification not less than once every two months for their reaction with the cement used (setting behaviour and strength decrease). In the case of accelerators in liquid form, their stability during storage shall be visually inspected and checked for crystallisation at similar intervals. Storage times and working temperature ranges shall be in accordance with the manufacturer's recommendations. The manufacturer's safety instructions shall be observed.

The required characteristic values and the regularity of delivery shall be agreed with the accelerator manufacturer before commencement of the shotcreting works.

Provided the characteristic strength requirements are met, accelerators can be dosed up to a maximum of:

- 10% by weight of cement for accelerators in powdered form
- 9% by weight of cement for accelerators in liquid form
- 15% by weight of cement for water glass

2.4.3 PLASTICIZERS AND RETARDERS

With the wet method, plasticizers and retarders may be used to reduce the quantity of the mixing water and to improve the pumpability of the concrete. The effects of the plasticizers shall be determined in site trials. Shotcrete made by using plasticizers and retarders shall be checked regularly for setting time, water reduction and the development of strength as compared with the base concrete.

2.5 Shotcrete Requirements

Shotcrete shall be capable of being applied in layers of up to 150 mm in thickness with good adhesion to the ground or to the previous layer of shotcrete, with a good bond to the reinforcement and without sagging.

The characteristic strengths shall be:

- 0.5 MPa after 30 minutes
- 6 MPa after 24 hours
- 22 MPa after 28 days

Strength requirements shall be based on core samples taken in both directions from the test panel for site trials and on cores drilled in the direction of shotcrete application for quality tests.

Shotcrete shall be dense and homogeneous without segregation of aggregates or other visible imperfections.
3. **Equipment**

3.1 **General**

The works may be performed using any type of equipment approved by the Engineer.

The entire equipment must have a valid quality control certificate and is to be inspected within regular inspection periods.

All transport pipes consisting of hoses or pipes of uniform diameter that carry shotcrete ingredients shall be laid straight or in gentle curves and protected so that the flow of ingredients through them is not restricted.

The shotcrete machine shall be adjusted to suit the length of the pipe that carries the shotcrete mix. The equipment shall be leak-proof. Residual deposits of materials shall be removed after each usage.

The air and water supply system shall be capable of supplying the delivery machine and hose at the pressures and volumes recommended by the manufacturer of the machine. No air supply system shall be used that delivers air contaminated by oil.

The shotcreting equipment shall be capable of feeding materials at a regular rate and ejecting shotcrete from the nozzle at velocities that will allow adherence of the materials to the surface being shotcreted and compaction of those materials with a minimum of rebound and maximum adhesion and density.

The placing equipment shall be arranged in such a way that the nozzleman may use air and water in any combination to prepare raw surfaces or to clean completed works.

Equipment shall be provided to allow application of shotcrete to all surfaces with the nozzle at the distances from the work specified in Subchapter 5.3, Shotcrete Application.

A boom mounting (robo-jet) or similar device shall be provided for the spray nozzle for use in conditions where manual spraying is unsafe or otherwise, unsuitable or undesirable.

3.2 **Equipment for Dry Method**

The nozzle shall be capable of controlling the quantity of water to be added and of ensuring effective mixing of all shotcrete ingredients.

Admixtures in powder form shall be added by means of mechanical batching devices located at the shotcrete machine. The batching device shall be capable of ensuring continuous accurate batching of the admixture. If necessary, it shall be possible to adjust the batches mechanically or manually for a larger or smaller quantity of admixture. The batching devices shall be protected against water, dust and weather and shall be cleaned at regular intervals.

Liquid accelerators shall be metered uniformly into the water. If this is carried out by pumps adding a specified quantity of accelerator to the water, special screens shall be incorporated to eliminate foreign substances.
3.3 **Equipment for Wet Method**

The equipment for the wet method shall be set up according to the recommendations of the manufacturer.

Pumping shall ensure a continuous conveyance of base concrete including any admixture except accelerators. The equipment shall incorporate a suitable metering device for liquid admixtures.

The accelerator shall be added close to the nozzle through an individual pipe.

4. **Transport**

All components shall be transported by suitable means of transport and in accordance with industrial safety and road traffic regulations to avoid any damage.

For shotcrete produced using the dry method, the dry mixture may be delivered by truck mixers or non-agitating transport units. The dry mixture shall be effectively protected against any influence exerted by weather.

For shotcrete produced using the wet method, the base concrete including any admixtures except accelerators shall be transported by any suitable means providing complete mixing during transportation such that segregation of the mix components is prevented. The mixture shall be effectively protected against any influence exerted by weather.

5. **Workmanship**

5.1 **Site Trials**

5.1.1 **GENERAL**

Site trials shall be started early enough to ensure that the required shotcrete mix is developed and all trials are completed satisfactorily by the time shotcreting commences in the works. Shotcreting shall not commence until the trials and the laboratory tests have been completed satisfactorily.

The site trials shall employ the equipment which will be used in the works and constituent materials shall be fully representative of those to be used in the works.

5.1.2 **DEVELOPMENT OF MIX DESIGN**

The design of the shotcrete mix shall be developed in two stages:

(a) Production of a suitable base concrete

(b) Production of shotcrete from the base concrete
The target mean strength for the base concrete shall be such that the strength reduction specified in Subchapter 2 is not exceeded for shotcrete with accelerator and that the specified strengths are achieved.

5.1.3 SHOTCRETING TRIALS

1) A trial mix shall be designed and prepared with the constituent materials in the proportions proposed for use in the works. Sampling and testing procedures shall be in accordance with the relevant specifications. A clean dry mixer shall be used and the first batch shall be discarded.

2) From the trial mix, an experienced nozzleman shall prepare sufficient test panels. Each panel shall be at least 600 x 400 mm in size and shall be 200 mm thick. The panels shall be prepared by shotcreting into vertical rigid plywood boxes. The shotcrete in the panels shall adhere well to the backform, be properly compacted and exhibit no sagging.

3) Cylindrical test specimens shall be cored from each test panel and tested as listed below. Drilling and dimensions of test specimens shall be in accordance with the relevant specifications. The drilling of cores shall be performed at locations, avoiding areas of possible rebound.

4) Cores to be tested at different ages (1 day (24 hours) and 28 days) may come from the same panel. For each test at least one spare specimen shall be provided.
   (a) Compressive strength in spray direction after 1 and 28 days on 4 cores each. The test cores shall be 100 mm in diameter and 100 mm in length.
   (b) Compressive strength perpendicular to spray direction after 1 and 28 days on 4 cores each. The test cores shall be 100 mm in diameter and 100 mm in length.

5) Target workability values shall be determined for the wet method.

6) Each cored cylinder shall be provided with a reference mark and the date and time of shotcreting.

7) The panels shall be stored without disturbance at a temperature between 10°C and 25°C covered by a polythene sheet until the time of coring. Cores for 1 and 28 days compressive strength tests shall be obtained from the panels at the same day. The cores for 28 day strength test shall be stored in water.

8) The testing for compressive strength shall be in accordance with the relevant specifications.

9) Additional test panels shall be prepared as necessary to calibrate indirect test methods approved by the Engineer or his delegated personnel. For the purpose of calibration, a minimum of four tests shall be carried out at each age for each indirect test method and shotcrete mix.

10) The strength of shotcrete cores from test panels shall be acceptable if both the compressive strength results for samples with their axes parallel to the direction of spraying and the compressive strength results for samples with their axes perpendicular to the direction of spraying comply with the following requirements.
(a) The average strength determined from the 4 cores from a particular trial shall be at least the specified characteristic strength.

(b) Any individual core strength result shall not be lower than the specified characteristic strength by more than:
   - 2.0 MPa for 1 day strength
   - 3.0 MPa for 28 day strength

11) The test results shall be passed to the Engineer or his delegated personnel responsible for the design of shotcrete structures.

12) The site trials shall be repeated if the source or quality of any of the materials or the mix proportions are changed.

5.1.4 PROFICIENCY OF OPERATIVES

The nozzlemen shall have had previous experience in the application of shotcrete, or shall work under the immediate supervision of the foreman or instructor with such experience. Production shotcrete shall be applied only by nozzlemen who have successfully demonstrated their competence and their ability to produce shotcrete complying in all respects with this Specification and have been issued a certificate indicating their competence.

5.2 Batching and Mixing

The individual components for the production of shotcrete shall be measured by weight with an automatic batching device, except liquid admixtures. They may be measured by volume. The batching accuracy shall be within 3% for cement, water and aggregates and within 5% for admixtures. The method of batching used shall ensure that the accuracy can be easily checked. The accuracy shall be checked at least once a month.

Mixing shall be carried out in a mixer suitable for the efficient mixing and discharge of dry or wet batched materials as appropriate. Regular checks shall be made to ensure that complete mixing is consistently achieved.

The mixing time for the dry method shall be sufficient to produce complete mixing and shall be not less than 1 minute. The mixture shall be delivered by means of appropriate equipment and segregation shall be avoided.

Mixed materials for the dry method may be used up to 3 hours after the addition of cement, provided that the shotcrete can be applied satisfactorily. After this time, any unused material shall be discarded. Testing according to Subchapter 6.1.1, Strength Tests to verify the strength of shotcrete used more than 2 hours after batching will be required.

Accelerators for the dry method shall not be added until immediately prior to depositing the materials in the placing equipment, or, if in liquid form shall be accurately proportioned into the water supply at the shotcreting equipment. The mixed base concrete for the wet method shall be applied within three hours, depending on the type of cement used and the temperature of the base concrete and the atmosphere. Retarders may be used to extend the time for placing. Accelerators for the wet method shall be added immediately prior to the application of shotcrete at the application nozzle.
**Shotcrete Application**

Before the application of shotcrete, the excavated surfaces shall be cleaned with compressed air and, as far as the local conditions permit it, with an air-water mixture as necessary to remove all material which may prevent proper adhesion of the shotcrete to the ground surface. Loose rock shall be cleared from behind the steel mesh. The surface to receive shotcrete shall be damp and where possible without free water prior to the application of shotcrete.

Action shall be taken where necessary to control groundwater and to prevent that it affects the shotcrete lining adversely. Water inflows which might cause deterioration of the shotcrete, or prevent adherence, shall be diverted by channels, chases, pipes or other appropriate means to the invert or to the groundwater drainage system.

Where necessary, pressure relief holes shall be provided through the lining to ensure that no hydrostatic pressure develops behind the lining.

Shotcrete shall only be applied by experienced nozzlemen. The preferred distance between the nozzle and the surface being shotcreted shall be 2.0 m with the dry method and 1.5 m with the wet method. The nozzle shall, as a general rule, be held perpendicular to the application surface. However, when shooting through reinforcing bars, the nozzle shall be held closer and at a slight angle in order to permit encasement and to minimise rebound.

No rebound material is to be covered with shotcrete and incorporated in the works. The rebound material shall be removed from the tunnel and shall not be reused in the works.

Each layer of shotcrete shall be built up by making several passes of the nozzle over the working area. The shotcrete shall emerge from the nozzle in a steady uninterrupted flow. Should the flow become intermittent for any cause the nozzlemans shall direct it away from the work until it becomes constant again.

Where a layer of shotcrete is to be covered by succeeding layers, it shall first be allowed to set and loose material and rebound shall be removed. The surface shall be finally cleaned and wetted using a blast of air and water.

For vertical and near vertical surfaces, application shall commence at the bottom. The thickness of the layer shall mainly be governed by the requirement that the material shall not sag. Where thick layers are applied, the top surface shall be maintained at a slope of approximately 45 degrees.

Shotcrete may not be applied through two or more layers of wire mesh except for laps between mesh panels, unless approved by the Engineer.

**Shotcrete Thickness**

The inner surface of shotcrete may follow the contours of the rock surface, with the necessary rounding of the edges and corners, provided that protruding, sound blocks of rock still firmly linked to the ground mass have a minimum shotcrete cover of the thickness specified in the drawings.

Steel arches, steel mesh and the like shall be surrounded with at least 30 mm of shotcrete unless otherwise shown on the drawings.
Any sealing shotcrete layer or flash coat shall be at least 20 mm thick, or as otherwise shown in the drawings or directed on site by the Engineer.

5.5 Reinforcement

Reinforcement mesh shall be securely fixed in place. The reinforcement shall be cleaned of any previously deposited material which might prevent a proper bond.

Ties, anchors and supports for the mesh shall be of steel and suitable spacers shall be provided where necessary. Timber packings shall not be used. The method of fixing the mesh shall be such that shotcrete can be compacted soundly behind the reinforcement at all points.

5.6 Application of Shotcrete in Cold Weather

When shotcrete is placed at air temperatures of less than 5°C, measures shall be taken to maintain shotcrete temperature above 3°C for at least 1 day after application.

No frozen materials, ice or snow shall be allowed to enter the mixer.

Cement shall not be heated. If water is introduced at the nozzle, it shall not be heated above 20°C.

5.7 Curing

Measures shall be taken to ensure that shotcrete exhibits proper strength gain and a minimum of cracking. Curing measures shall be applied as necessary to achieve these requirements.

6. Quality Control

All components must have a valid quality certificate and a valid permission for the intended use.

6.1 Works Tests

6.1.1 STRENGTH TESTS

Compressive strength tests shall be performed on cores taken from shotcrete in the works. The time of coring shall be as close as possible to 24 hours after placing. Cores required for 28 day strength tests may be obtained at the same time as those for 1 day strength tests and stored in the laboratory.

The frequency of coring shall be such as to obtain 3 cores each for 1 and 28 day tests for every 200 m² of shotcrete used in the works. Depending on the compliance of test results with this Specification, the circumstances of application and the importance of construction, the frequency of work tests and the amount of test sets may be reduced (to every 500 m³, 1 and 28 day strength respectively) or increased (to every 100 m³) subject to previous approval of the Engineer or his delegated personnel. The cores shall be drilled through the whole thickness of
the shotcrete and visually inspected to verify that the shotcrete is dense and homogeneous without segregation of aggregate or other visible imperfections.

Reinforcement incorporated in the in-situ shotcrete may lead to improper test specimens (e.g., too much wire mesh, rebound traps), which must not be used for testing. Samples should therefore be taken at different points of the in-situ shotcrete. Individual values deviating by more than 15% from the arithmetic mean must be disregarded. For computing the arithmetic mean, at least three proper samples must be available.

Instead of testing cores taken from shotcrete placed in the works, indirect penetration and pull-out test methods may be used to determine the 1 day strength of shotcrete as approved by the Engineer. Tests for 1 day strength shall be carried out between 22 and 48 hours preferably at 24 hours ± 2 hours. Individual calibration has to be developed specifically for the test equipment used. The test results shall be related to the characteristic strength of one day. Mechanical rebound hammers shall not be used to determine the indirect compressive strength of shotcrete.

Where the nominal required shotcrete thickness is less than 100 mm, the cores for compressive strength testing shall be taken from areas where the actual thickness is greater than 100 mm. Alternatively, additional shotcrete thickness shall be applied in selected areas for subsequent test coring as directed by the Engineer.

The strength of shotcrete measured by cores taken from the works (or by indirect test methods as specified above) shall be acceptable if the compressive strength results comply with the following requirements:

(a) The average strength for any group of four consecutive test results shall be at least the specified characteristic strength.

(b) Any test result (mean of 3 core strengths) shall not be lower than the specified characteristic strength by more than:

   2.0 N/mm² for 1 day strength
   3.0 N/mm² for 28 day strength

If the shotcrete fails to meet the compliance requirements specified herein, the validity of the test results shall be checked prior to implementing one of the following courses of action:

(a) Confirm the requirements for remedial action by assessing the results of geotechnical measurements and/or back-analyses.

(b) Make good deficiencies by the application of additional shotcrete thickness at past or future works until compliance with the requirements is confirmed.

(c) Following an approved procedure, remove the defective shotcrete and replace by new shotcrete.

(d) Install additional rock dowels – if needed

The course of action to be adopted shall be approved by the Engineer.

The hardening of young shotcrete shall be checked by penetration tests and / or Kaindl Meyco tests at timely intervals.
6.1.2 STABILITY TESTS

Tests shall be carried out once, at the beginning of works with a new shotcrete design mix, to assess the load-bearing capacity of the shotcrete in the works under site conditions. These tests may be carried out on cores taken from panels.

One set of tests shall be carried out for each mix type.

These panels shall be produced in the works under site conditions. The panels shall be stored underground in the works (with the same climatic conditions as the shotcrete placed in situ). Core samples shall be taken from the panels just before testing, or at least on the same day as testing.

Cylindrical test specimens shall be cored and tested as listed below. The dimensions of the test specimens and the testing procedure shall be in accordance with Subchapter 5.1.3, Shotcreting Trials.

(a) Compressive strength in the spray direction after 1 and 28 days on 3 cores each.

(b) Modulus of elasticity in the spray direction after 1 and 28 days on 3 cores each. The core shall be 100 mm in diameter and 200 mm in length. The strain shall be measured on the central part of the sample, the upper test limit being and the lower test limit being of the compressive strength.

The modulus of elasticity at different ages shall be determined on the same sample, the compressive strength being measured after 28 days.

If the stability of the tunnel is endangered because shotcrete does not meet the specified strength requirements, the affected shotcrete shall be replaced carefully or where practicable the deficiencies shall be compensated by the application of additional shotcrete or rock dowels as approved by the Engineer.

6.1.3 WORKABILITY TESTS

The workability of shotcrete produced by the wet method shall be measured by slump tests following the addition of plasticizer. Samples shall be tested for every 50 m³ produced.

The target workability values shall be determined during site trials.

The workability of wet method shotcrete shall be within ± 25 mm or ± one third of the target value, whichever is the greater.

6.1.4 THICKNESS TESTS

The thickness of placed shotcrete shall be checked using studs, double headed nails, or steel mesh bars bent perpendicular to the surface. Where closely spaced lattice girders (< 1.6 m) are used, no other routine shotcrete thickness check will be required.
5.2 Testing of Materials

5.2.1 TEST PROCEDURE FOR BLEEDING OF CEMENT

Put exactly 98 g of water with a temperature of 20°C into a 250 ml glass beaker with a small magnetic stirring rod. At medium stirring rate add 115 g of cement little by little within 20 seconds. Combine the mixture for 2 minutes until a homogeneous, relatively thin cement paste (water/cement ratio = 0.85) has been achieved.

Fill the homogenised mass into a 100 ml measuring cylinder up to the 100 ml index mark by means of a glass rod (do not pour directly into cylinder). It is absolutely necessary that the measuring cylinder be kept in a higher glass beaker filled with water of 20°C during the entire period of testing. Fluctuations in temperature shall not exceed ± 2°C.

After 120 minutes the amount of cement that has settled can be read from the scale, i.e. the amount of supernatant water may be determined. The reading is in ml corresponding to % by volume of repelled water.

6.2.2 TESTING OF ACCELERATORS

Setting Time

The dosage of accelerator, as % by weight of cement required to provide an initial setting of 60 sec ± 20 sec and a final setting of 150 sec at a maximum shall be determined in accordance with the following procedure.

(a) The temperature of the cement and water shall be 20°C ± 1°C.

(b) 1200 g of cement shall be placed in the mixing bowl of a mortar mixer (Hobart 5 litre mixer).

(c) When testing powder accelerators, the powder shall be weighed and then added to the cement in the mixing bowl and mixed on speed no. 1 for 2 minutes to ensure even distribution. Liquid accelerators shall be added to the mixing water.

(d) 420 ml of water shall be added to the mixture in the bowl within approximately 2 sec with the mixer on speed no. 1. After 5 sec the mixing speed shall be changed to no. 2 for a further 15 sec.

(e) The cement paste shall be taken from the mixing bowl by means of a spatula and placed in a vicat mould and lightly tamped to ensure no entrapped air is present in the sample. The top surface shall be struck off level and the mould shall be placed on the vicat apparatus within 20 sec upon completion of mixing (i.e. 40 sec upon addition of water).

(f) The initial set shall be determined in accordance with EN 196-3 and the final set shall be determined by continuing the use of the initial set method and recording the time at which the needle penetrates the top surface by less than 1 mm. The times shall be measured from the moment of water addition.

(g) If the initial set is less than 40 sec or more than 80 sec or the final set is more than 150 sec, the test shall be repeated using a smaller or higher dosage of accelerator.
Strength Decrease

The testing of the strength decrease for the selected type(s) of accelerator shall be carried out at the following dosages to establish the variability with dosage:

Dry Method

- accelerators in powder form: 3.0, 5.0, 7.0%
- accelerators in liquid form: 2.0, 4.0, 6.0%

Wet Method

- water glass: 8.0, 12.0, 15.0%
- accelerators in liquid form: 2.0, 4.0, 6.0%

The above percentages are by weight of cement.

At the dosage chosen for use in the works, the decrease in strength at an age of 28 days, as determined in Subchapter 2.9.2 - Testing of Accelerators, shall not exceed the following:

- accelerators in powder form maximum 45%
- accelerators in liquid form maximum 30%

The decrease in strength shall be determined according to the following procedure:

Mortar cubes shall be used in accordance with EN 196-1.

A comparison of the 7-day and 28-day strengths of mortar shall be carried out as follows:

- The strength shall be determined without accelerator (A)
- The strength shall be determined with accelerator adopting the dosage used for the setting time tests (B)

The decrease in strength is \( \frac{A - B}{A} \times 100 \)

Mortar Tests - With Accelerator

The mortar strength with accelerator shall be determined in accordance with the following procedure:

(a) The temperature of the mortar constituents shall be: 20° ± 1°C.
(b) 370 g of mix water shall be poured into the dry mortar mixing bowl.
(c) Accelerator shall be added to and blended with the mix water at the dosage determined in accordance with 2.9.2, Item 1 - Setting Time.
(d) 1,710 g of standard sand shall be added to the water in the mixing bowl with the mixer running at low rotation speed.

(e) 570 g cement shall be poured into the bowl within 5 sec and the mortar mixer shall immediately be switched to high speed for a mixing time of 30 sec.

(f) The moulds shall be filled with mortar as quickly as possible. The mortar shall be compacted by vibration for a period of 15 seconds only.

(g) The bulk density of the compacted mortar cubes shall be determined and compared with the bulk density of mortar cubes prepared without accelerator in order to check whether the appropriate compaction has been achieved. (The maximum admissible difference of bulk density to cubes prepared without accelerator shall not exceed ± 5%)

(h) The cubes shall be removed from the moulds at an age of 4.5 hours and stored in a moist curing chamber at 20°C.

(i) Compressive strength testing of the specimens shall be undertaken after 7 and/or 28 days.

**Mortar Test - Without Accelerator (Basic Mortar Mix)**

The compressive strength of mortar cubes without accelerator shall be determined. The following mix ratio shall be used:

- 370 g water
- 570 g cement
- 1,710 g sand

7. **Measurements**

The quantity survey unit of the shotcrete shall be m³. The volume (thickness) depends on the individual excavation and support type executed. The respective values are documented in the corresponding drawings.

8. **Acceptance**

8.1 **Conformity of Work with Design and Technical Specification**

The works shall be carried out in accordance with the design, with the Technical Specification and the written instructions of the Engineer.
8.2 **Acceptance of Works To Be Removed or Covered**

8.2.1 **DOCUMENTS AND DATA**
The acceptance of works which are to be removed or covered shall be based upon:
- a written statement by the Engineer entered into the Site Book that the works have been executed in accordance with the design and the Technical Specification(s),
- other written statements by the Engineer commenting on the execution of the works.

8.2.2 **SCOPE OF WORKS**
The scope of works to be removed or covered shall be determined by written statements of the Engineer and by other documents confirmed by the Engineer.

9. **Applicable Regulations**

9.1 **Standards**

**Canadian Standards**
CSA 23.1-94 Materials and method of concrete construction

**German Standards**
DIN 267 Fasteners and similar parts, technical specifications, generalities
DIN 1045, ENV 206 Structural concrete
DIN 1164 Portland - blast furnace - pozzolanic cement, definitions, components, requirements, delivery
DIN 18200 Control (quality control) of construction materials, construction components, and construction designs; general principles
DIN 18851 Shotcrete – fabrication and testing

**European Standards**
EC 2 Design of concrete structures
EN 196 Methods of testing cement

1 Introduction

1.1 Subject of Technical Specification
This Technical Specification (TS) shall define the requirements for the execution and
commissioning of all monitoring measures at the Niagara Tunnel Facility Project.

1.2 Range of Technical Specification Application
This TS is a bid and contract document used for the execution and commissioning of the works
referred to in Item 1.1.

The provisions contained in this Specification refer to the working methods to be adopted for
the:

a) delivery of all the components including the entire material and equipment required to the
site
b) installation of all the components within the construction sequences
c) measuring of individual parameters as required
d) evaluation and interpretation of the results obtained
e) quality control for material and workmanship.

The Scope of Works is defined for the construction period in both the main tunnel and the
corresponding adjacent structures (e. g. intake, outlet) as well as for the monitoring activities
during the operation period.

1.3 Definitions
The basic definitions given in this TS are in conformity with the relevant standards in force. The
monitoring measures are separated into measures executed during construction and measures
performed during operation.

1.3.1 Monitoring during Construction Period
The monitoring objectives during construction are:

a) To check the adequacy of ground support in tunnels and excavations and to determine any
support modifications required.
b) To determine the effects exerted by the construction work on the existing structures below
ground, forming part of the works.
c) To check the adequacy of initial and final tunnel linings, and of various structural elements
of underground structures.

Monitoring shall continue throughout the life of the contract with the objective to evaluate
whether the behaviour of the underground structures and the ground conditions actually
complies with the design expectations, to ensure that safety is maintained, and to assist in defining the scheduling and implementation of necessary maintenance tasks.

The following monitoring activities shall be carried out throughout the works as a minimum requirement:

a) Deformations of tunnel linings and junction openings
b) Deformations of adjacent structures
c) Ground movements adjacent to the tunnel
d) Groundwater pressure adjacent to the tunnel

1.3.2 Monitoring during Operation Period

The monitoring during operation shall meet the following objectives:

a) to evaluate the adequacy of ground support in tunnels and excavations
b) to verify the long-term loadings and the long-term underground behaviour
c) to monitor the load-bearing capacity of the structure

Monitoring shall continue throughout the facility's life cycle to ensure that the load-bearing capacity of the structures is maintained and to assist in defining the scheduling and implementation of necessary maintenance tasks.

The following monitoring activities shall be carried out as a minimum requirement:

a) Ground movement adjacent to the tunnel
b) Groundwater pressure adjacent to the tunnel

1.4 General Work Requirements

The Contractor shall be responsible for the quality of material and workmanship and for their conformity with the Design Documentation, other corresponding Specifications and Method Statements and the Engineer's instructions.

The Contractor shall make suitable allowance in his overall work programme for the installation, testing, calibration, reading, and maintenance of instruments, the interpretation of field readings and the implementation of appropriate corrective measures. The monitoring program shall extend over the entire construction and maintenance period.

Notwithstanding any other provisions in the contract in respect of the Contractor's staff, the personnel responsible for the installation, testing, calibration, reading, maintenance and surveying of the instruments, shall be qualified and experienced in the field of instrumentation, geotechnical monitoring and survey, as appropriate.

The Contractor shall provide his instrumentation personnel with all the equipment necessary in accordance with the Specification and shall grant them access to the works to enable them to carry out their work in a safe and proper way at the appropriate time intervals stipulated in this Specification.
1.4.1 PROVIDION OF MEASURING DEVICES

The Contractor shall present an organisation chart and time schedule of the works to the Engineer for approval. These documents shall give due consideration to all the conditions accompanying the performance of the measurements and the presentation of results.

All equipment and installation accessories, required for the operation of the instrumentation system and the recording of measurements, shall be supplied by the Contractor and shall be available on site prior to any construction works being performed in the area in which they are to be installed and shall be stored securely where they will not suffer any physical damage or any damage arising from excessive moisture, temperature extremes or other adverse conditions.

All measuring devices shall be as specified and shall be manufactured by companies with a proven record of experience in the field of tunnel and/or geotechnical instrumentation. All materials, designs and constructions shall be of the highest quality to provide robust, corrosion and vibration resistant instruments. Instruments embedded in concrete linings shall be capable of withstanding vibrations from compacting equipment (e.g. shotcrete application). The accuracy and dependability of the equipment shall not be significantly affected by changes in temperature, humidity, stray currents or other adverse conditions that may be encountered. Calibration certificates, where appropriate, shall be provided by a reputable testing company.

1.4.2 INSTALLATION AND MAINTENANCE OF INSTRUMENTS

The location and type of instruments shall be as shown on the Drawings or as otherwise specified.

The location and arrangement of the instruments shall be planned so that monitoring can continue, if specified, after completion of the works with all electrical and mechanical equipment etc. in place. Adequate access for maintaining and reading the instruments shall be provided. Remote control instruments should be capable of being read without interruption to other site activities.

A stock of additional instruments shall be available and installed as found necessary in the event of unforeseen conditions being encountered, for which more extensive monitoring might be required.

The Contractor shall install the equipment according to the manufacturer’s recommendations. Testing shall be undertaken as necessary to ensure satisfactory functioning of the equipment at each stage of the installation. In particular, adequate precautions shall be taken to protect the instruments against harmful effects resulting from construction works and groundwater seepage. Instruments found to be malfunctioning at any time shall be replaced at the earliest opportunity.

All instruments shall be securely fixed in accordance with the Drawings and their Specifications including any attendant wiring and terminal panels, and shall be adequately protected against mechanical damage and ingress of water and dirt.

As far as practicable, instruments and terminal boxes built into concrete linings shall be kept clear of reinforcement.
The installation of instrumentation in underground excavations shall be carried out at the earliest opportunity, following the advance of the tunnel face, consistent with the needs to ensure safe working methods and adequate equipment protection.

The Contractor shall take every practical measure to prevent damage to the instruments and ancillary equipment during handling, installation and subsequent operation. The Contractor shall maintain all the instruments required for long-term monitoring in a satisfactory working order for the entire duration of the monitoring program.

The readout boxes shall be capable of being placed at adequate distances to their associated transducers without the specified accuracy of the instrumentation being impaired.

Measures shall be taken to ensure that electrical instruments will not be adversely affected by other temporary or permanent electrical services.

1.4.3 INSTRUMENT READING AND RECORDS

A logical reference system for all instrumentation equipment shall be established by the Contractor so that records for any particular location can easily be recovered for interpretation or review.

Instruments shall be read as soon as possible after installation to obtain datum readings, which shall be established from a minimum of two independent reading operations producing consistent results. Datum readings and reading frequencies specific to a particular instrument are stated in the relevant chapter describing the details and the use of the instrument.

Readings shall continue to be taken once each day until the rate of change in the readings falls off sufficiently to allow a lower frequency to be adopted with confidence that the safety of the works is not in doubt and that the amount of data retrieved will allow trends with time to be clearly identified and evaluated.

In the event of any change in circumstances, for example the influence of the construction on other structures nearby or of junctions and openings, the reading program shall be resumed.

In particular during excavation of a tunnel in the vicinity of an instrumented ground section, daily readings shall be resumed not later than four days before the working face reaches the instrumentation section and in any event once the working face is within 50 m of the instrumented section.

Where seasonable considerations are expected to influence the instrument readings, at least four readings per year shall be taken.

When recording instrumentation readings, all site conditions that may affect the results shall be recorded, including temperature, air pressure and humidity, temperature of recently placed concrete, progress of excavation, progress of other construction activities such as lining erection and grouting, time lapse between construction and taking of first readings, tunnel air movements, machinery vibration, activity and progress in adjacent tunnels. Instrument type, location reference, data and time of reading, personnel carrying out the readings, measuring instruments or readout unit references shall also be recorded.
Instrument readings shall be recorded on record sheets designed for this purpose or preferably directly on tape, disc or any other digital storing device for subsequent computer analysis. Corrections shall be made for temperature difference or other factors as appropriate. Immediately after the readings have been taken, the measurement results shall be entered into time-deformation and time-stress diagrams respectively, to evaluate the stability behaviour of the underground structure.

The diagram used shall also show:

a) the project title
b) the type of measurement, e.g. deformation, extensometer, piezometer.
c) the diagram page reference
d) the location and chainage of the measuring points
e) a sketch of the tunnel cross-section, clearly marking the position of the measuring points.
f) the details of the excavation process such as:
   • distance of measuring point from the face
   • excavation of crown, bench and invert in relation to the measurements
   • location of adjacent openings
g) the duration shall be recorded between the excavation and the datum reading taken at the measuring section
h) new datum readings shall be clearly indicated.
i) the scale of diagrams shall be uniform and shall not be changed with the magnitude of measurement results.

The same recording devices, e.g. tape extensometers, pressure gauges, digital readouts, etc. shall be used at any given location throughout the monitoring program. If for any reason this becomes impractical, due to instrument breakage for example, new datum readings shall be taken immediately with a replacement instrument, i.e. the new instrument used for the future readings. Similarly, should a monitoring location become unavailable, the instrument previously read from this point shall, as soon as practicable after becoming unavailable, be read from an alternative point, the latter than being used for subsequent readings.

Readings shall, wherever possible, be taken by the same personnel. Should the person need to be replaced for any reason, a series of duplicate readings shall be carried out by the out-going person and his replacement.
2 Materials

2.1 General

A detailed statement of the types and sources of manufacture of the geotechnical measurement components, proposed for use in the works, shall be prepared.

The instrument manufacturer shall provide drawings and data describing the principal features, the mode of operation, the measuring range and the degrees of accuracy of the equipment. The manufacture of all items shall be in accordance with the Drawings and the Specification(s) provided.

Where instruments shall be capable of being monitored remotely by portable remote readout units, the readout units and the appropriate plug-in leads shall be compatible with the instruments being monitored. The readout units shall plug into appropriate readout boxes.

2.2 Technical Requirement of Instrumentation

2.2.1 GENERAL

The instruments to be used for the monitoring of underground structures shall include but shall not be limited to:

a) Theodolite and targets to measure the lining deformations (for general use)
b) Levelling studs and geodetic levelling equipment (if theodolite for optical measurements is not used)
c) Tape extensometer (if theodolite for optical measurements is not used)
d) Rod extensometers
e) Piezometers

2.2.2 CONVERGENCE MEASURING INSTRUMENTS

The convergence measuring bolts shall be made of high-yield tensile steel with a quality corresponding to the reinforcement quality. The top shall have a screw thread for a target or geodetic levelling stud or the pin of a tape extensometer to be fixed to it.

The tape extensometer to be used shall be made of corrosion-proof metal and fitted with a dial gauge and tensioning device. It shall be suitable for measuring over the required lengths and in any direction from a measuring bolt. It shall have a resolution of 1 mm and shall be capable of measuring absolute lengths to an accuracy of ± 1 mm.

Levelling studs shall be manufactured from stainless steel and fixed to the tunnel linings in the same manner and to the same standards as convergence reference points. Geodetic levels shall have robust tripods. They shall be designed in such a way that their use in conjunction with the appropriate geodetic instruments allows precision levelling to an accuracy of ± 1 mm.
The theodolite used for convergence measurements shall have an accuracy of $\pm 1$ mm.

2.2.3 ROD EXTENSOMETER

Rods shall be fabricated from aluminium alloy or glass-fibre reinforced resin. The cross-sectional dimensions of the tunnel shall not be a restriction to the maximum extensometer length to be installed.

Extensometers shall be designed in such a way that the measurement of both elongations and reductions in the length between anchorage point and measuring head are possible. The head of the extensometer shall be exchangeable.

Reading facilities shall be either:

- portable mechanical measuring devices which shall include a dial depth gauge and a calibration device. The accuracy of the device shall not exceed 0.1 mm and the measuring range shall be $\pm 15$ cm.

or

- electric displacement transducers for remote reading from a terminal box with an overall accuracy of 0.1 mm and a measuring range of $\pm 15$ cm. The transducers shall be waterproof to full hydrostatic head.

The cabling terminal box shall be capable of accepting up to four extensometers. A battery-operated digital readout device capable of reading to the required overall accuracy shall also be provided. The readout equipment shall be compatible to the measuring system and shall ensure an automatic data acquisition throughout the operation period.

2.2.3 PIEZOMETER

The piezometer shall be of a type and manufacture approved by the Engineer. The piezometer used shall be of the vibrating wire (v/w) type. It shall be made of stainless steel and shall include a stainless sintered filter.

The piezometer shall be installed in such way that it will be exchangeable throughout the facility's life period. The readout equipment shall be compatible to the measuring system and shall ensure an automatic data acquisition throughout the operation period.

The piezometer shall be capable of measuring the water head at the piezometer tip to a repeatability of $\pm 0.1$ m.

3 Equipment

The works may be performed using any type of equipment approved by the Engineer.

The entire equipment must have a valid quality control certificate and is to be inspected within regular inspection periods.
4 Transport

All components of the monitoring equipment shall be transported by suitable means of transport and in accordance with industrial safety and road traffic regulations to avoid any damage.

5 Workmanship

5.1 General

This section relates to the instrumentation to be provided to aid in determining the support necessary for the excavation in accordance with the use of the New Austrian Tunnelling Method (NATM) and the use of the Tunnel Boring Machine (TBM).

The instrumentation shall be installed as soon as practicable in the cycle of excavation and underground support. It shall be adequately protected against mechanical and environmental damage and shall be accessible at all times for survey purposes.

The Contractor's instrumentation personnel shall be responsible for all measurements and for proper data recording. There shall be staff based on site, available any time during construction, and capable of analyzing the data in terms of adequacy and in relation to the actual ground support measures. The results shall be entered into diagrams in compliance with the requirements of the Engineer responsible for ground support. The diagrams shall be updated immediately after a set of measurements has been completed to permit an evaluation of the stability of the structure.

At locations where lining stresses and ground pressures are measured, lining deformations shall be recorded as well.

Provisions in the final lining for a continued monitoring of the instrumentation shall be made as specified by the Designer.

Details describing the installation of the instruments shall be recorded, such as the exact position and orientation of the instruments, the length and orientation of possible drill holes, the shotcrete thickness and the ground formations encountered at the measurement location.

5.1 Details and Use of Instruments

5.1.1 DEFORMATION MEASUREMENTS (CONVERGENCE MEASUREMENTS)

Lining deformations shall be monitored by observing the movement of measuring bolts installed immediately after excavation. Measuring bolts shall be fixed during the tunnel advance, before or after shotcrete application.

The following measurements shall be taken:

a) Optical measurements generally using a theodolite
b) Tape measurements, especially where optical measurements cannot be taken

Deformation measurements shall be taken in sections of up to 500 m along the tunnel. The positioning of the measuring bolts shall be adjusted to suit the excavation sequence adopted.

Deformation results shall be assessed in conjunction with a visual examination of the tunnel surfaces to record signs of distress such as cracks and sections of splitting and falling ground or a loosening or overstressing of support measures. Subject to the findings of both, the deformation results and any signs of distress, any adjustment to the existing support shall be made in accordance with the design and subject to the Engineer’s approval.

The ambient temperature shall be taken at the time of each reading. The instrument shall be used and read in accordance with the manufacturer’s instructions. Three dial gauge readings shall be taken and recorded for each measurement and averaged prior to making the temperature correction.

The instrument shall be checked against a calibration bar before and after each set of readings. If a convergence line becomes unavailable, e.g. due to final service installations obstructing the measurement, dual readings shall be taken with its replacement. If this is impossible due to construction works, then readings shall be taken on the old line at the latest possible time and the new line shall be established and read as soon as possible.

5.1.2 ROD EXTENSOMETERS

Rod extensometers employed in the works shall take the following form:

A rod anchored at the remote end of a drill hole shall pass into a plastic tube fixed in a reference collar at the open end of the hole. The relative movement between the end anchor and the reference collar shall be measured with either a dial gauge or an electric transducer on the free end of the rod. A range adjustment device fitted at the reference collar shall extend the reading range beyond that of the dial gauge. In case this multiple arrangement is employed, it shall be calibrated on one single rod extensometer installed in close proximity. Rods are installed in a single hole with each rod of a different length so that displacements at various drillhole depths may be recorded. Each rod shall be individually isolated by its own plastic sleeve. The complete assembly shall be grouted in place, fixing the anchors to the ground but allowing free movement of each rod within its sleeve.

A single reference housing shall receive all rods from one drillhole and provide protection to the reference head. The number of rods per drillhole shall be as shown on the drawings.

Other characteristics of the instrument shall be as follows:

The anchor points shall be according to the manufacturer’s recommendation.

The extensometers shall be installed to the lengths shown on the drawings, where the lengths specified refer to the overall lengths of rod plus anchorage bar.

The accuracy of drilling shall be such that the drill hole shall be straight and shall not deviate from its intended orientation by more than four degrees.
5.2 Evaluation, Interpretation

5.2.1 REPORTING

The Contractor shall compile a weekly summary of geotechnical records and monitoring measurements which shall contain such comments as:

a) comparison with design expectations
b) schedule of measurements taken
c) any unusual circumstances
d) any special measurements taken during the previous week of construction

5.2.2 DESIGN ASSESSMENT

The Contractor shall be responsible for the interpretation of geotechnical measurements such as the comparison of measuring readouts and calculation results. The Contractor shall issue processed monitoring results promptly and regularly. He shall immediately inform the Designer of any discrepancies between calculation results and actual results and shall make recommendations for a design variation.

In case of serious discrepancies arising between the calculated and the measured results, a back-analysis shall be initiated to confirm these discrepancies and in a subsequent step, the structures still to be built shall be re-analyzed.

6 Quality Control

All components must have a valid quality certificate and a valid permission for the intended use.

The Contractor shall be responsible for keeping records of all calibration certificates and for sending equipment off site for recalibration by reputable testing laboratories when required.

The Contractor shall ensure that the entire instrumentation in use has been correctly calibrated. The Contractor shall also carry out periodic checks to confirm the validity of equipment calibration in accordance with the manufacturer's instructions and to carry out adjustments if found necessary. Suspect readings shall be repeated.

7 Measurements

The quantity survey unit of the measuring device shall be piece (installed measuring device). The quantity survey unit of the measurements and readings shall be piece (measurement) per measuring point.
8 Acceptance

8.1 Conformity of Work with Design and Technical Specification
The works shall be carried out in accordance with the design, the Technical Specification(s) and the written instructions of the Engineer.

8.2 Acceptance of Works To Removed or Covered

8.2.1 DOCUMENTS AND DATA
The acceptance of works which are to be removed or covered shall be based upon:
- a written statement by the Engineer entered into the Site Book that the works have been executed in accordance with the design and the Technical Specification(s),
- other written statements by the Engineer commenting on the execution of the works.

8.2.2 SCOPE OF WORKS
The scope of works to be removed or covered shall be determined by written statements of the Engineer and by other documents confirmed by the Engineer.

   9.1 Standards .................................................................. 11
1. **Introduction**

1.1 **Subject of Technical Specification**

This Technical Specification (TS) shall define the requirements for the execution and commissioning of underground grouting measures performed inside the Diversion Tunnel, at the intake and outlet structures and from the ground surface to achieve a ground improvement and a reduction in ground permeability at the Niagara Tunnel Facility Project.

1.2 **Range of Technical Specification Application**

This TS is a bid and contract document used for the execution and commissioning of the works referred to in Item 1.1.

The provisions contained in this Specification refer to the working methods to be adopted for the:

a) delivery of all the components and the entire equipment required to the site
b) drilling of boreholes for the grouting works required
c) mixing of the grouting components (materials) required
d) injection of planned underground space
e) quality control for material and workmanship.

The Scope of Work is defined for the Diversion Tunnel during excavation and support.

1.3 **Definitions**

The basic definitions given in this TS are in conformity with the relevant standards in force.

1.3.1 **BOREHOLES**

The boreholes for the grouting measures can be installed by hammer drilling or rotary drilling. Boreholes in poor ground, which are not stable, have to be cased with tubes à manchette (perforated pipes with rubber sleeves).

The diameter of boreholes with casing must be such as to allow for the installation of tubes à manchette (dia 50 mm) and screen pipes (dia 50 mm) before recovery of the casing.

Borings without casing are only admissible if the ground is firm enough to prevent the borehole from caving in. The drilling diameter is to be selected to permit the use of packers being inserted by means of pipes with a diameter of 20 mm.

1.3.2 **GROUTING COMPONENTS**

The main components for underground grouting are:

- water
• cement
• sand

In addition,
• bentonite
• additives like hardeners or plasticizers
• chemical components like water glass

can be used for special requirements to be met. The individual components are specified in Subchapter 2, Materials.

1.3.3 GROUTING EQUIPMENT
For grouting, the following equipment components will be needed on site:
• mixing plant
• pumping system
• injection lines
• packers
• measuring facilities

The components listed are specified in Subchapter 3, Equipment.

1.4 General Work Requirements
The Contractor shall be responsible for the quality of material and workmanship and for their conformity with the Design Documentation, other corresponding Specifications and Method Statements and the Engineer’s instructions.

The Contractor shall provide his personnel with the equipment necessary in accordance with the Specification and shall grant them access to the works to enable them to carry out their works in a safe and proper way.

Grout injections may be carried out from the ground surface or from the tunnels. Special care is to be taken to ensure that the injection (grouting) equipment is selected and installed in a way, which does not impair existing utilities, structures and buildings.

Before commencing the grouting works, the Contractor shall propose a concept for these works. The concept shall comprise the equipment envisaged, the scope of work and the grouting work stages, the selection of grouting material, as well as the injection pressures and rates to be applied.
2. **Materials**

2.1 **General**

The suitability of the individual materials for the respective ground and grouting operation must be verified by testing.

2.2 **Water**

The water used for grouting works must not contain more than 1.5 % of soluble substances. The percentage of sulfates must drop below 1 %. Water polluted by organic substances is not suitable for the execution of grouting works. In order to determine chemical processes in the water, adequate water analyses shall be carried out prior to the works.

The water temperature during mixing and grouting should range between 5°C and 25°C.

2.3 **Cement**

Only cement with a suitable fineness of grinding shall be used. The Blaine value should at least amount to 3200 cm²/g. The compatibility of cement, bentonite and water shall be verified.

In exceptional cases, special rapidly setting cements with a high degree of grinding fineness may be used to stop water seepage. The time span until the material starts to set should not exceed 20 minutes.

2.4 **Bentonite or Clay Powder**

In case of grouting with bentonite, non-activated bentonite or clay powder shall be used. The mix proportions, regarding the share of bentonite as well as that of water in the suspension, depend on the swelling properties of bentonite or clay powder. 90 % of the bentonite grain fraction should be smaller than 2 µ and the compatibility of cement and bentonite shall be closely observed.

2.5 **Sand**

Only fine sand with largely round grains and without organic components within a grading range between 0.1 and 1 mm may be used. The percentage of grains smaller than 0.1 mm must not exceed 10 %.

2.6 **Additives**

The use of grouting additives is subject to approval by the Engineer. Before works are started, the compatibility of additives with cement and bentonite as well as with the water used, shall be verified by laboratory tests.

Only technically acknowledged additives, which have been successfully employed for similar works and do not carry any harmful implications upon application, shall be proposed by the Contractor.
2.7 Chemical Injections

Chemical injections may be executed with water glass or acrylic resin unless otherwise proposed by the Contractor. Water glass with 37° - 39° Blaine shall be used. Hardeners may be on an organic basis or may be soda lye with sodium aluminate. The gelling time must be variable between 1 minute and 2 hours.

2.8 Suspensions

With cement-bentonite suspensions or pure cement suspensions, the water/binder ratio should range between 0.6 and a maximum of 2. Suspensions with a larger water content are not admissible.

The cement-bentonite suspensions used should be largely stable, i.e. the degree of settling must not exceed 10%.

3. Equipment

The works may be performed using any type of equipment approved by the Engineer.

The entire equipment must have a valid quality control certificate and is to be inspected within regular inspection periods.

3.1 Mixing Plants

The site equipment shall include mixers and pumping equipment to allow for uninterrupted stirring of any grouting material (e.g. cement, bentonite, water glass or resin solution). Even in case of a power failure or any similar disturbance, a constant stirring of the injection material must be guaranteed.

The dosage of single components of the grout mix shall be measured by means of scales or volumetrically in a way to achieve an accuracy of 1 - 2% in relation to the smallest portion of the mix. For the agitation of suspensions, colloidal mixers with a high rotation rate (1200 to 1500 rotations per minute) shall be used.

The duration of the mixing process must suit the respective grouting material but should at least be 2 minutes.

3.2 Pumping System

The injection pumps must be adjustable with respect to both pressure and flow rate. The use of pressure cylinders is not admissible. In case of piston pumps, equalising tanks shall be installed to avoid pressure surges during pump operation. The pumping rate should at least come to 60 l/min at a maximum pressure of 50 bar. It must moreover be possible to add sand or other fine inert material to the cement suspension.
3.3 Measuring Facilities

Each mixing station shall be equipped with a pressure and flow rate recorder for each single pump. These devices shall serve to monitor the grouting process and to record operational data of each grout injection unit.

All pressure gauges used on site must be calibrated. The display range shall correspond to the pressures required and applied.

3.4 Injection Lines

A feeder line and a return line must be installed between each pump and the borehole. Thus the grouting material may circulate in the line system in case of failure and in case of any interruption of the grout injection process. A pressure gauge must be placed at the borehole mouth allowing for a direct reading of the pressure applied. Each pump must not inject more than one section of a borehole. In order to avoid sedimentation of grouting material and uncontrolled mixing or changes in the mix proportions within the line, injection lines with a diameter of 20 mm shall be used.

Furthermore, telephone communication between the borehole mouth and the pumping station should be operative at all times. The entire system shall be designed for an operation pressure of 50 bar (5 MPa).

Before starting grout injections or water pressure tests, the recorders installed in the mixing container and the pressure gauges located on the pumps and at the borehole mouth must be checked.

3.5 Packers

Once pressure is applied, the packers must be in tight contact with the borehole or grouting tube wall. The length of the packers shall be chosen in a way preventing dislocations during water tests or grout injections. The specified cross-section of water/grout flow must not be reduced at any location.

For grout injections or water pressure tests during drilling operation, single packers shall be employed. For grout injections and for water tests in completed boreholes twin packers shall be used.

All sealing elements must be available with appropriate diameter and in sufficient quantity. Using double packers, the injection length may be variable.

4. Transport

All components shall be transported by suitable means of transport and in accordance with industrial safety and road traffic regulations to avoid any damage.
5. Workmanship

5.1 Injection Works
Grouting a ring or an array of boreholes shall be carried out adopting the following sequence:

If two rings of drill holes shall be injected, grouting will first be applied to the inner ring, before the outer ring will be grouted. At the first stage, only every second borehole will be grouted. Intermediate boreholes not yet grouted will be used to check the efficiency of the grout injection.

The injection pressure shall be selected according to the ground conditions. The pressures applied must never lead to ground fracturing. If faced with an accidental fracturing of the ground, the pressure employed for further grout injections shall be reduced to 80% of the pressure which caused the fracturing.

The pumping rate in low-permeability ground shall amount to 50 – 70 l/min, while for injections in strongly fissured ground a maximum pumping rate of 65 l/min shall be admissible.

5.2 Tube à Manchette Installation
Boreholes which have to be equipped with a casing will be equipped with perforated pipes with rubber sleeves arranged at a certain spacing (tube à manchette). The system and design of these pipes will be subject to the Engineer’s approval.

The space between the borehole and the tube à manchette will be filled with cement suspension which, in the case of cased boreholes, must be applied when the casing tubes are extracted.

The composition of the cement suspension is to be suggested by the Contractor. The following information may serve as a guideline:
water: 884 l
bentonite: 75 kg
cement: 270 kg

The suitability of the mixture is to be verified on site and is to be approved by the Engineer.

Generally, the tubes à manchette shall be rinsed after each injection to keep them operable until the completion of the works. Following the completion of these works, the tubes à manchette are to be filled with cement-bentonite suspension.

5.3 Monitoring
A detailed log containing information on the grouting works executed shall be prepared separately for each single borehole and shall be submitted to the Engineer. The logs are to contain the following information:

• Indication of location
• Identification number of borehole
6. Quality Control

All components must have a valid quality certificate and a valid permission for the intended use.

6.1 Suitability Test

Laboratory tests shall ensure that all requirements are met in the application of chemical injections as well as suspensions. The samples to be analyzed shall be prepared by the use of standard sand. The following characteristics shall be determined:

- Viscosity
- Settling characteristics
- Compressive strength
- Permeability
- Viscosity limit for injections (suspension viscosity is measured with a funnel, resin viscosity with a rotary cylinder viscometer)

Sample cubes of 50 x 50 x 50 [mm] shall be prepared and placed in water. The compressive strength shall be tested after 7 and after 28 days.

6.2 Quality Test

Upon injection of water glass or resin solutions, samples shall be taken from each mixing batch indicating hour, location of use, identification number of borehole, and position of sleeve within the borehole. In case of cement-bentonite suspensions, samples shall be taken from the mixing plant to be analyzed in the laboratory.
6.3 **Control of Workmanship**

The efficiency of the injections shall be verified by water pressure tests carried out in intermediate boreholes. The results shall be compared with the results of water pressure tests carried out before the grouting operation started.

In case of uncertainty about the success of the grouting operation, additional confirmatory boreholes shall be drilled.

6.4 **Water Pressure Tests**

6.4.1 **GENERAL**

Water pressure tests are to be performed in rock. In soil they may be realised in exceptional cases.

Generally, water pressure tests are conducted at three pressure stages. The tests are to be extended over sections of 3 m or less, if necessary. In case of boreholes with single packers, the tests may proceed in drilling direction, in case of boreholes with double packers, the tests may be carried out in reverse direction following the completion of a borehole.

6.4.2 **EXECUTION OF WATER PRESSURE TESTS**

Installations for water pressure tests are to be designed for a maximum pressure of 25 bar. The pressure is measured with a pressure gauge. The water consumption is determined by use of a water meter. The water pressure applied is measured at the borehole mouth. Additionally, the following data are to be recorded at each test:

- Elevation of pressure gauge = borehole mouth
- Elevation of packer
- Pressure loss in pipe from borehole mouth to discharge through holes in sealing element (calibration of sealing element)

The pressure to be applied depends on the hydrostatic pressure prevailing in joints and voids. The pressure stages are determined on the basis of the maximum pressure, with the first stage amounting to a quarter and the second stage amounting to one half of the maximum pressure. The third pressure stage corresponds to the maximum pressure selected. On the falling side, in turn, half of the maximum pressure and at the last stage a quarter thereof are to be applied. Measurements may only be commenced after a state of equilibrium has been established, i.e. as soon as the pressure gauge indicates a steady pressure and the discharge of water is constant. At that point, the pressure has to be maintained for 5 minutes and the amount of water injected must be read from the water meter.

The results yielded by the water pressure tests shall be recorded in graphic form with all the characteristic data being included in the respective log. The graphic representation should be in the form of a pressure/flow rate diagram.
7. **Measurements**

   The quantity survey unit of the grouting measures shall be

   - t (weight) for the materials,
   - m (length) for the drilling of boreholes, differentiating between drilling inside the tunnel in all directions and drilling from the ground surface and graded in such steps as “up to 5 m, up to 10 m, up to 15 m, up to 30 m”.
   - h (time) for the ground injecting in phases, the time basis being the pump's operation time.
   - piece for the delivery and appropriation of the whole equipment to the execution site and between the execution sites

8. **Acceptance**

8.1 **Conformity of Work with Design and Technical Specification**

   The works shall be carried out in accordance with the design, the Technical Specification and the written instructions of the Engineer.

8.2 **Acceptance of Works To Be Removed or Covered**

8.2.1 **DOCUMENTS AND DATA**

   The acceptance of works which are to be removed or covered shall be based upon:
   - a written statement by the Engineer entered into the Site Book that the works have been executed in accordance with the design and the Technical Specification(s),
   - other written statements by the Engineer commenting on the execution of the works.

8.2.2 **SCOPE OF WORKS**

   The scope of works to be removed or covered shall be determined by written statements of the Engineer and by other documents confirmed by the Engineer.

1. **Introduction**

1.1 **Subject of Technical Specification**

This Technical Specification (TS) shall define the requirements for the execution and commissioning of interface grouting measures for the prestressing of the final lining of the Diversion Tunnel of the Niagara Tunnel Facility Project.

1.2 **Range of Technical Specification Application**

This TS is a bid and contract document used for the execution and commissioning of the works referred to in Item 1.1.

The provisions contained in this Specification refer to the working methods to be adopted for the:

a) delivery of all the components and the entire equipment required to the site
b) joint installation of grouting hoses and waterproofing system
c) mixing of required grouting components (materials)
d) injection of annular space between shotcrete lining and waterproofing system at the specified pressure
e) quality control for material and workmanship.

The Scope of Work is defined for the Diversion Tunnel during construction of the final lining.

1.3 **Definitions**

The basic definitions given in this TS are in conformity with the relevant standards in force.

1.3.1 **GROUT HOSES**

Synthetic pipes, with a nominal internal diameter of 15 mm and a wall thickness of approx. 3 mm, shall be provided at the interface between the shotcrete lining and the waterproofing membrane of the tunnel. The installation shall be carried out together with the installation of the waterproofing system.

The grout hoses are generally installed in rings at a uniform spacing along the tunnel.

1.3.2 **MANCHETTES**

The grout hoses are fitted with reinjectable outlet valves, termed manchettes, comprising 5 mm thick soft rubber sleeves, 200 mm long and covering groups of three 5 mm diameter holes drilled at intervals along the pipe. The manchettes are generally spaced at 3,000 mm centres and are fixed in position to prevent sliding.
1.3.3 PVC JACKETS
To facilitate the distribution of grout into the interface, the grout hoses fitted with the manchettes are installed in a jacket of PVC sheet with a thickness of 250 microns and a circumference of 900 mm. The jackets have been carefully fixed to the prepared surface through metallic strips approximately spaced at 500 mm centres.

1.3.4 CONNECTION POINTS
The ends of the grout hoses, which shall stick out of the Diversion Tunnel’s final lining concrete face, shall be provided with a 25 mm diameter I.S.O. or similar female threaded socket fitted with a screwed plug and installed flush with the concrete surface.

The Contractor shall provide suitable tools and equipment to make all connections necessary to these embedded sockets during interface grouting operations. Care shall be exercised at all times to avoid damage to the permanently embedded sockets.

The sockets shall be closed with caps once the interface grouting operation is finished.

1.3.5 GROUT BLOCKING RINGS
For the grout not to proceed too far from the points of injection, grout blocking rings shall be installed every 12 m. A grout blocking ring consists of a piece of geotextile fleece, which is not backed by any synthetic material. The geotextile fleece is folded to not less than four layers and fixed to the shotcrete surface around the circumference of the tunnel.

1.3.6 GROUTING COMPONENTS
The main components are:
- water
- cement

The individual components are specified in the Subchapter 2, Materials

1.4 General Work Requirements
The Contractor shall be responsible for the quality of material and workmanship and for their conformity with the Design Documentation, other corresponding Specifications and Method Statements, as well as the Engineer’s instructions.

The Contractor shall provide his personnel with the know-how and equipment necessary in accordance with the Specification and shall grant them access to the works to enable them to carry out their work in a safe and proper way. All interface grouting operations on site shall be performed by skilled workmen under the direct and continuous guidance and supervision of foremen and engineers relying on extensive experience in this type of work.

Before commencing the interface grouting works, the Contractor shall propose a concept for these works. The concept shall comprise the equipment envisaged, the scope of work and the
grouting work stages, the selection of grouting material, as well as the injection pressures and rates to be applied.

Interface grouting shall only be commenced once contact grouting has been completed and once the specified concrete strength for the final lining has been attained.

2. Materials

2.1 General
The suitability of the individual materials for the respective ground and the grouting operation must be verified by testing.

2.2 Water
The water used for grouting works must not contain more than 1.5 % of soluble substances. The percentage of sulfates must be below 1 %. Water polluted by organic substances is not suitable for the execution of grouting works. In order to determine chemical processes in the water, adequate water analyses shall be carried out prior to the works.
The water temperature during mixing and grouting shall range between 5°C and 25°C.

2.3 Cement
Ordinary Portland cement with a suitable fineness of grinding shall be used. The Blaine value shall at least amount to 3200 cm² / g. The quality strength of the cement (strength, hardening time) shall correspond with the working conditions required and the ultimately pressure required.

2.4 Suspensions
The water/binder ratio of the suspension shall range between 0.5 and 2.0. Suspensions with a larger water content are not admissible.
The suitable water/binder ratio in the different pressure stages shall be examined by trials.

3. Equipment
The works may be performed using any type of equipment approved by the Engineer.
The entire equipment must have a valid quality control certificate and is to be inspected within regular inspection periods.
3.1 Grout Mixer

A two-compartment high-speed colloidal mixer such as the Colcrete mixer or any equivalent shall be used for grout mixing. The grout shall be mixed in one compartment and discharged through strainers into a holding tank of suitable capacity. From the holding tank the grout shall pass through further strainers into the suction end of the grout pump. Provision shall be made to keep the grout in the holding tank continuously agitated by mechanical means.

The mixer(s) shall be of sufficient capacity to ensure that the grout pumps do not run dry at any time.

3.2 Pumping System

The grout shall be injected by means of an approved double-acting reciprocating pump or any other type of approved pump, equipped with interconnecting pipes and valves in a way permitting a stand-by pump and water supply equipment to be brought into immediate service as may be necessary to provide continuous injection of a hole or connection point. Grout pumps shall be capable of smoothly injecting grout at any pressure up to 30 bar. Air vessels shall be incorporated in the equipment arrangement to dampen surges in grouting pressure.

Pressure relief valves shall be incorporated in the system to avoid the possibility of injection at pressures in excess of that specified or instructed for the point being grouted.

The grouting equipment shall be such that the rate of delivery and/or pressure can be readily and precisely adjusted down to zero flow and that the grout consistency can be readily adjusted without causing any interruption of sufficient duration to allow the pumped grout to set.

For interface grouting through grout hoses, it is envisaged that the main grout mix is pumped with the aid of high-pressure pumps to a holding tank with mechanical agitation, forming a component of the local underground grouting unit. The capacity of the transport pumps shall be equal to twice the capacity of the underground grouting unit.

At the underground working point in the tunnel, for example, not less than three grouting pumps (plus stand-by pumps) each with a minimum capacity of one litre per second at 30 bar allowing good pressure control (such as Peroni pumps) shall be provided. A properly functioning pressure relief valve shall be fitted on each pump delivery to control and limit the grouting pressure.

For filling and pressurising the grout hoses and grout seals ahead of an interface grouting operation and for flushing the grout hoses after grouting a separate hydraulic pump (20 bar capability) with a capacity of five litres per second shall also be provided at each working location.

3.3 Injection Capacity at Working Point

Each grouting unit installed at the individual points of injection, including the mixing plant or the holding tank, the pump and the associated pipes shall be capable of delivering not less than 60 litres of liquid grout per minute at a pressure of 30 bar.
For interface grouting operation, the delivery capability of the grouting unit provided at the working point shall not be less than 180 litres of liquid grout per minute at a pressure of 30 bar when utilising three injection pumps in parallel.

The actual quantity of grout required per minute shall be validated at the interface grouting trials to be carried out.

3.4 Water Tank
Each and every grouting unit employed on site shall include a water storage tank of adequate capacity to be used for a flushing of the pumps, pipes and grout hoses, etc.

3.5 Mobile Grouting Platforms
The use of mobile grouting platforms by the Contractor is envisaged for an efficient working performance in the tunnels. Only suitable mobile platforms shall be employed to move injection equipment into position in order to avoid damage to the finished surfaces of the concrete lined Diversion Tunnel. All mobile platforms shall be provided with suitable hauling and braking devices.

3.6 Grouting Communication
Where the various elements of a grouting unit are located in such positions that verbal communication at normal voice level between the pump and the hole or connection point to be grouted is not satisfactory, the Contractor shall install a verbal communication such as a telephone and shall operate and maintain the communication equipment to ensure efficient and satisfactory service at all times.

3.7 Measuring Facilities
Pressure gauges shall be fitted to the grout pump and to a point approximately one meter ahead of the grout hose connection point.

A pressure/time diagram recording plotter of approved make shall be installed at a position approved by the Engineer on the delivery pipe from each pump injecting grout.

A water meter of approved type, indicating quantities of half a litre, shall be installed in all supply mains to measure the mixing water.

A flow meter to measure the grout volume injected during interface grouting operations shall be installed in the pipework arrangement for each grouting unit.

The Contractor shall arrange for an adequate number of pressure gauges, pressure/time diagram recording plotters including charts, water meters and flow meters correctly calibrated to be available on site, preventing grouting operations to be held up at any time due to a lack of accurately calibrated instruments.

The pressure gauges shall have a range not exceeding twice the expected maximum pressure for a particular grouting stage and shall have an accuracy of plus / minus three per cent.
Two certified pressure gauges together with calibration equipment by an approved authority for re-calibration purposes and one hundred per cent replacement stock of working pressure gauges shall be on hand at all times. The certificated pressure gauges shall not be used for grouting.

Working pressure gauges shall not be used for longer than two twelve hour shifts after which time they shall be cleaned and re-calibrated. All working gauges shall be clearly numbered for identification purposes.

4. Transport

All components shall be transported by suitable means of transport and in accordance with industrial safety and road traffic regulations to avoid any damage.

5. Workmanship

5.1 Grouting Works

The composition of the grout mixture for interface grouting operations shall be approved by the Engineer.

Interface grouting of a defined section of the works shall be carried out without interruption day and night until completed.

At the point of injection, one end of each segment of the grout hose ring shall be connected to one grouting pump. The other end of each segment shall be connected to the return flow manifold and shall lead to a holding tank. Each preset ring shall be equipped with stop valves and pressure gauges. Alternatively a four-way valve arrangement allowing control of the grouting operation from the pump may be approved for adoption.

Generally three preset rings in the tunnel shall be interconnected and grouted simultaneously, requiring a grouting unit of three working pumps. The preset rings shall be connected at alternate positions, in a way that every other ring is grouted clockwise or anticlockwise respectively.

The grouting operation shall commence at the first group of preset rings with full pump capacity. As the absorption of grout decreases, the injection pressure slowly increases. To prevent clogging of the preset rings in those sections of the pipe where there may be little or no flow, the stop valves at the return flow end of the preset ring shall be opened briefly to purge the line. This operation shall be repeated at ten minute intervals or at such intervals as on-going experience indicates to be adequate.

When the specified pressure is reached and no more grout is absorbed, the grouting pump shall be disconnected, flushed with water and connected to the other end of the preset ring, where the same procedure is applied in reverse direction of the preset ring. When the specified pressure is reached again and no more grout is absorbed, the grouting pump shall be disconnected and leapfrogged forward to be connected to the next grout hose.
The grouted ring shall be flushed with water and the embedded sockets shall be closed off with permanent screw plugs. In case of satisfactory results of the interface grouting operation and if the preset grouting ring is not anticipated to be used again, final flushing with water will not be required.

Generally, the injection shall be judged to be satisfactory if the grout take on any ring drops to below one litre per minute at the specified pressure.

Generally the speed of grouting advance along the Diversion Tunnel should not exceed three to four metres per hour.

It is anticipated that the interface gap induced by the specified grout pressure will be in the order of 2 - 3 mm, equivalent to a convergence of 3 - 5 mm on the internal diameter of the Diversion Tunnel's final concrete lining. The Contractor shall plan his operations in the tunnel to cater for a total rate of grout injection of up to 8,000 litres of fluid mix per hour at the start of grouting when the pressures will be much less than the specified maximum.

In the event that the surrounding rock absorbs only a small quantity of grout and the specified pressure is likely to be attained rapidly, the injection rate shall be reduced to permit a dissipation of excess water to take place and to maintain the four metre speed of advance mentioned previously.

In the event that the grout travel is not sufficiently restricted due to leakage into fissures or through the final concrete lining and the pressure is unable to build up to the specified maximum or the anticipated convergence of the lining is not obtained, the injection of grout shall be stopped and the preset grout hose rings shall be flushed out. After a period of three hours or any other period determined by the Engineer, the preset rings shall be pressurised with water and the manchettes shall be cracked open to ensure that they will be injectable.

When directed by the Engineer within a period of 24 hours, the preset rings shall be reconnected and grout injection shall recommence.

This procedure shall be repeated as necessary until the specified pressure is maintained and/or the anticipated convergence is achieved.

In the event that interruption to the work is unavoidable through causes beyond the control of the Contractor, the grouting of the last preset ring shall be finished in the specified manner and flushed out.

After such an interruption the grouting shall be restarted approximately 10 metres ahead of the section previously injected and carried out in a backward direction with a single grout pump until the last completely injected preset ring has been reached. The remaining grouting pumps shall normally be used in the forward direction where this is practicable in the Diversion Tunnel.

Any significant leakage from the final concrete lining which is not self-sealing shall be by-passed and treated and the area shall be grouted again through flushed out preset rings until the specified pressure and/or convergence is attained.
5.2 Grouting Procedure

Where shown on the drawings, interface grouting through grout hoses shall be carried out to prestress the rock surrounding the concrete lining and to prestress the final concrete lining in a way that internal water pressure shall not cause adverse cracking of the final concrete lining.

The grouting works shall be carried out making initial injections in every second ring. The remaining rings in between shall be used as back-up system. If satisfactory convergence of the final concrete lining is not obtained, the back-up rings shall be grouted as directed by the Engineer.

5.3 Monitoring

A detailed log containing information on the grouting works executed shall be prepared separately for each single pressure ring and shall be submitted to the Engineer. The log is to contain the following information:

- Reference number and location of grouted preset rings.
- Details of grout injections indicating pressures, grout consistencies, grout volumes injected, quantities of material injected and injection times throughout the period of injection.
- Details of grouting processes adopted, surface leaks, interconnections and reflux.
- Charts from the recording pressure gauges.

6. Quality Control

All components must have a valid quality certificate and a valid permission for the intended use.

6.1 Grouting Trials

6.1.1 PURPOSE OF TRIALS

The trials are designed to establish operational procedures for the interface grouting to ensure optimum prestressing of the linings in the Diversion Tunnel.

6.1.2 SCOPE OF TRIALS

It is intended that the trials will be carried out on seven 12-metre-long adjacent concrete bays approx. at km 7.3 in the Diversion Tunnel.

6.1.3 PROCEDURES

Before embarking on the trial grouting, the Contractor shall - in consultation with the Engineer - develop a detailed statement of the procedures to be followed during the grouting trials.

The trial grouting will provide the following information:
(a) Suitability of grout and interface grouting arrangement
(b) Pressure required to initiate grout travel
(c) Rate of travel and how it may be controlled by injection procedures
(d) Grout take with respect to geological conditions
(e) Asymmetrical deformation of the lining and how this may be controlled
(f) Number of rings to be injected at any one time and pressures in individual rings
(g) Monitoring procedures
(h) Adequacy of acceptance criteria

The trials will be evaluated by the Engineer by means of instrumentation installed within the concrete lining and surrounding rock as well as by grout injection characteristics.

The results of this evaluation will be used to develop optimum operational procedures.

6.1.4 INSTRUMENTATION
A typical instrumentation layout is shown on proposal drawing PD-01-1008. Each instrumented cross-section will be in the centre of a 12 metre concrete bay. The scope of the instrumentation shown corresponds to the sections, subjected to the highest stresses. Other sections will be similar but will involve fewer instruments.

6.2 Quality Control of Works
In order to check the efficiency of the grouting measures, monitoring will be carried out at representative locations in the Diversion Tunnel. This monitoring will typically involve the following methods:

(a) Verification of available records
(b) Precise monitoring of convergence in vertical and horizontal axes during grouting of a section.
(c) Piezometer measurements at locations where such instruments have been installed, prior to concreting, to observe tunnel conditions.
(d) Extensometer measurements at locations where such instruments have been installed, prior to concreting, to observe tunnel conditions.

7. Measurements
The quantity survey unit of the grouting measures shall be
- $m^3$ (volume) for the suspension,
- $h$ (time) for the injection in phases, the time basis being the pump’s operation time.
8. Acceptance

8.1 Conformity of Work with Design and Technical Specification
The works shall be carried out in accordance with the design, the Technical Specification(s) and the written instructions of the Engineer.

8.2 Acceptance of Works To Be Removed or Covered

8.2.1 DOCUMENTS AND DATA
The acceptance of works which are to be removed or covered shall be based upon:
- a written statement by the Engineer entered into the Site Book that the works have been executed in accordance with the design and the Technical Specification(s),
- other written statements by the Engineer commenting on the execution of the works.

8.2.2 SCOPE OF WORKS
The scope of works to be removed or covered shall be determined by written statements of the Engineer and by other documents confirmed by the Engineer.

9.1 Standards ............................................................................................................................. 2016
1. **Introduction**

1.1 **Subject of Technical Specification**

This Technical Specification (TS) shall define the requirements for the execution and commissioning of the final lining for the Diversion Tunnel at the Niagara Tunnel Facility Project.

1.2 **Range of Technical Specification Application**

This TS is a bid and contract document used for the execution and commissioning of the works referred to in Item 1.1.

The provisions contained in this Specification refer to the working methods to be adopted for the:

a) delivery of all the components and the entire equipment required to the site

b) installation of formwork required

c) execution of concrete works

d) quality control for workmanship and material.

The Scope of Work is defined for the Diversion Tunnel during the construction of the final lining.

1.3 **Definitions**

The basic definitions given in this TS are in conformity with the relevant standards in force.

1.3.1 **FINAL LINING CONCRETE**

For the concrete composition, Canadian standards shall mainly be applicable. A concrete with high abrasion resistance shall be produced. In addition to this, the following requirements shall be met:

- The release strength (= concrete strength at formwork removal) shall be 3 MPa, reached after 12 hours.
- The concrete composition shall be selected in such way that development of internal restraint stresses as a result of hydration will be minimized and the required release strength of 3 MPa will be reached within said 12 hours, without it being significantly exceeded.

- The concrete composition shall be suited to meet the respective seasonal conditions (summer, winter). Should this not be possible with one composition, two special compositions shall be developed.

- The concrete composition shall consider the placing of concrete behind the horse-shoe shaped formwork. Especially the flow characteristics and the concrete’s "bleeding" effect will have to be taken into account.

The concrete bay length is planned to be 12 m at a maximum. The final concrete lining will not be reinforced. The final lining will be prestressed with high-pressure grouting at the interface between the waterproofing membrane and the shotcrete lining.

1.3.2 FORMWORK

A formwork with a smooth surface shall be used. Special attention is to be paid to the sealing of joints and to the concreting windows. The shutter length (= formwork construction length) should be in the range of 12 m.

Both, formwork and formwork joints will have to be completely tight to prevent the leakage of grouting material. Both, formwork joints and formwork skin joints will have to be spaced at regular intervals.

Preference is given to steel formwork. Wooden formwork may not be exposed to the sun and to wind for excessive periods of time. The formwork should be fixed on a shutter which is designed to the requirements of the concreting procedure.

Within the formwork skin, windows and hoses for concreting behind the formwork have to be provided in sufficient number and in a way ensuring a sufficient filling of the concrete bay under all project conditions.

The formwork system in general is subject to the Engineer's approval.
1.3.3 JOINTS

All joints shall be butt joints and placed according to the drawings.

Due to the tunnel alignment and the straight course of the formwork, there will be an offset within the joints in the curves. This offset size should be minimized by readjusting the shutter and shall not exceed 77 mm (theoretical value) at a maximum.

1.3.4 CURING

Until the concrete is sufficiently hardened, it is to be protected against detrimental influences – for example excessive warming, drying out due to sun or wind, running water, chemical attack, frost.

1.3.5 CONTACT GROUTING

Following the concrete setting, there will be some porous cavities especially in the crown of the tunnel. These cavities will have to be filled with grout. For this task to be accomplished, hoses will be installed in the crown behind the final concrete lining, attached to the waterproofing membrane. Fittings will be provided at each end of the concrete bay.

Along the hoses, rubber sleeves with grout flow openings will be installed at a mutual spacing of less than 3 m.

1.3.6 INTERFACE GROUTING

For a pre-stressing of the final concrete lining, high-pressure grouting at the interface of the waterproofing system and the shotcrete lining will be carried out. For this task, a separate specification is available.

1.4 General Work Requirements

The Contractor shall be responsible for the quality of material and workmanship and for their conformity with the Design Documentation, other corresponding Specifications and Method Statements and the Engineer’s instructions.
The Contractor shall provide his personnel with the know-how and equipment necessary in accordance with the Specification and shall grant them access to the works to enable them carry out their work in a safe and proper way.

Before commencing the concrete works, the Contractor shall propose a concept for these works. The concept shall comprise the equipment envisaged, the scope of work and the work stages.

2. Materials

2.1 Aggregates

Aggregates shall be taken from a source approved by the Engineer. The mixture of the aggregates shall be uniform without gap grading. The gravel (coarse) fraction shall be of cubic crushed or rounded form.

Aggregates shall be hard, durable, non-porous and clean and shall not be chemically reactive. They shall not contain any deleterious material in sufficient quantity to adversely affect the strength at any age or the durability of the concrete or to cause corrosion of reinforcement.

The grading and the shape of the aggregates shall be such that a concrete can be produced with the specified proportions and consistency, which will readily work into position without segregation and without the use of excessive water and which can readily be compacted into a dense impervious mass.

The nominal maximum aggregate size shall be 16 mm. The gravel fraction of the aggregate shall not exhibit excessive fragmentation during delivery. The percentage of brittle grains shall be less than 5%. The percentage of particles smaller than 0.06 mm, which can be washed away, shall not exceed 1%.

Sand and gravel shall be clean. Frozen aggregates shall not be used. The minimum permissible temperature shall be +3°C. Should the aggregates be warmed using steam, special attention shall be paid to controlling the moisture content, particularly in the sand fraction.

All aggregates shall have a specific gravity of not less than 26 kN/m³.
The grading curve shall comply with the curve determined during suitability tests. The deviation of the given specified gradation should not exceed the values listed below.

Table: Deviation from grain particle size

<table>
<thead>
<tr>
<th>Grain Diameter</th>
<th>Admissible Deviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.06 mm</td>
<td>+/- 1 %</td>
</tr>
<tr>
<td>0.25 mm</td>
<td>+/- 1 %</td>
</tr>
<tr>
<td>1 mm</td>
<td>+/- 2 %</td>
</tr>
<tr>
<td>4 mm</td>
<td>+/- 3 %</td>
</tr>
</tbody>
</table>

2.2 Cement and Cementing Materials

It is of particular importance to use cement of uniform chemical composition and uniform fineness. Before commencement of delivery, the required characteristic values are to be agreed upon by the Engineer with the cement manufacturer. For the entire cement delivered, the manufacturer shall make the cement analyses and the standard test results available.

The cement shall be ordinary Portland cement, rapid hardening Portland cement or Portland pulverized fuel ash cement. The cement type shall be 20 according to the C.S.A. Standard 23.1–00.

In addition, the cement used should satisfy the following requirements:

(a) Initial setting time not less than three hours.

(b) Fineness: Not less than 340 m²/kg; if content of pulverized fuel ash greater than 20 %, not less than 380 m²/kg.

(c) Bleeding: not more than 20 cm³ (Heidelberg Method); if content of pulverized fuel ash greater than 20 %, not more than 15 cm³.
(d) Compressive strength after one day (24 h ± 1 h) on mortar cubes: not less than 9 N/mm²

(e) The temperature of the cement at the time of use in the mixing plant must not be higher than 60°C.

If cementing materials (like fly ash) are used, their suitability to meet the special requirements of the final concrete lining will have to be tested and the results will have to be approved by the Engineer.

2.3 Water

The water shall be clean and free of harmful matter in such quantities, as would affect the properties of concrete in the plastic or hardened state.

The water shall satisfy the requirements of potable water.

2.4 Admixtures

Admixtures added to the concrete, must not affect the concrete’s hardening, strength and durability or cause corrosion of the reinforcement.

Chlorides or materials containing chlorides which promote steel corrosion may not be added to reinforced concrete or concrete which comes into contact with reinforced concrete. The prerequisite for the use of admixtures is a qualification test to be performed by the Contractor. The test results must be submitted to the Engineer.

2.5 Concrete

The concrete mix design should meet the following requirements (according to C.S.A 23. 1–00):

- concrete with high abrasion resistance and limited heat of hydration
- water / cement ratio ≤ 0.45
- aggregates size 0 mm to 16 mm
- recommended cement volume 300 kg / m³
2.6 Contact Grouting Material

The contact grouting material shall be a cement–water suspension with sufficient fluid characteristics to fill the porous cavities and annular space between the final concrete lining and the waterproofing membrane.

If other materials are used, they have to be consistent with the concrete. The consistency has to be demonstrated by test or by approved documents and the use of alternative materials has to be approved by the Engineer.

3. Equipment

The works may be performed using any type of equipment approved by the Engineer.

The entire equipment must have a valid quality control certificate and is to be inspected within regular inspection periods.

The design and construction of the formwork shutter has to be evaluated by approved documents (calculations and drawings) and a check of the shutter by a Professional Engineer. The results have to be certified by the Engineer.

4. Transport

All single components shall be transported by suitable means of transport and in accordance with industrial safety and road traffic regulations to avoid any damage.

The concrete must not separate while being transported to the construction site and it shall be of the required workability at the location and time of placing.
5. Workmanship

5.1 General

Before starting the concrete works, the Contractor shall develop a concrete works program, which shall contain information on the

- type of concrete production, on site, ready mix
- distance of external plants to the site
- capacity of the mixing plants, additional plants for substitution (incl. distance to the site)
- testing procedure, suitability tests, quality control tests
- thermal development of the concrete during hardening
- schedule of concreting, simultaneous concreting on different sites
- concrete works procedure – use and preparation of formwork, cast in place procedure (progress, vibration, quality supervision)
- formwork replacement (concrete requirements)
- curing procedure

The concrete works program has to be submitted to the Engineer for approval.

5.2 Formwork

The formwork must be thoroughly cleaned before use. Before concreting, appropriate shutter oil is to be applied in such a way that no concrete sticks to the formwork.

Any formwork support materials subject to rust or corrosion are to be removed upon striking of the formwork. Any reinforcement or support materials remaining in the concrete must be rust and corrosion-proof.

Particular care must be taken in the construction of formwork for the end face of the concrete bays to ensure that the shuttering is especially tight. Without exception, shuttering for end faces must be of smooth-planed boards with parallel, tongue-
and-groove jointing; the forms must have a minimum thickness of 20 mm and must be of uniform width. Joints are to be so tight as to be unrecognisable, and the finished wall surface is to be perfectly smooth and even.

The formwork has to be erected and stabilized in such a way, that all stresses and strains caused by the concrete works can be covered. After erection and stabilization, the formwork will be surveyed for to its “correct” installation. The “correct” installation will be approved by the surveyor.

The construction element may only be stripped and the support may only be removed when the concrete has sufficiently hardened. The concrete has sufficiently hardened when the element is strong enough to support all loads, to which it is subjected when stripped, with the prescribed safety.

5.3 Concrete Works

5.3.1 CONCRETE PRODUCTION, SITE MIXING PLANT

The aggregates have to be stored on site in separate boxes for gravel, coarse sand and fine aggregates. They have to be protected against dryness, wetness and freezing. For the production of all types of concrete, the individual aggregate’s components are to be measured by weight using automatic dosing equipment.

The cement and the additives shall be stored in such way that they will be protected against seasonal influences and that they will keep their original state of quality at the time of delivery. For the concrete production, the components are to be measured by weight, using automatic dosing equipment.

The concrete mixing plant is to be laid out for a separated and automatic batching of 3 different additives. To permit monitoring of the levels of additives added to the concrete mixture, a transparent gauge glass is to be foreseen.

The concrete components (cement, aggregates, water and additives) must be measured with an accuracy of 3%. The weight batching machines shall be carefully maintained and cleaned and provided with simple and convenient means of checking the weighing mechanisms plus they shall be checked when required by the Engineer.

The composition of each type of concrete to be mixed is to be posted at the mixing plant in a clearly legible form and must include the requirements of the given
standards. The materials must be mixed in concrete mixers which are suitable for the pertinent concrete composition. The concrete mixer must be equipped with an electrical current indicator to facilitate regulation of the concrete's consistency. If the specific water content of the aggregates varies, the amount of wet material plus the amount of mixing water must always be selected in such a way, that the total amount of water remains constant.

The dimensions of the mixing plant have to be sufficient to deliver enough concrete to all relevant sites at any time of the concreting process. The concrete components and the concrete production have to be protected from extreme weather conditions (heat, rain). Mixing plants for sites located in cold weather areas, which may experience frost periods, are to be equipped with mixing water and aggregate heating systems.

A site laboratory, fully equipped to carry out all concrete and concrete component tests required, is to be set up and operated by experienced personnel. An expert in concrete technology and concrete production shall be in charge of this laboratory.

Test mixes are to be made for each type of concrete. The results are to be submitted to the Engineer. The mixes shall be approved by the Engineer and a trial mix shall be prepared under full-scale conditions, including workability tests and cube testing.

5.3.2 READY-MIXED CONCRETE

The entire ready-mixed concrete shall meet the requirements described in this Specification. In addition to this, the Contractor shall submit the name and address of the ready-mix Contractor to the Engineer for approval, giving all operation and plant details.

The details of the ready-mix Contractor shall include information on the plant, the equipment, the storage depots, as well as the transportation and quality systems. The Engineer shall have access to the ready-mix site for inspection at any time. The Engineer may reject the proposed ready-mix Contractor and may cancel an approval at any time, if the quality of the concrete or the documentation of the quality control is not satisfactory in the opinion of the Engineer.

All testing of the mixed concrete shall be executed on site.
The Contractor shall ensure that the supplier keeps records of all the required tests and the quality control for mixing and transportation.

The concrete shall be delivered to the site in truck mixers or agitators which are continuously in operation. Each batch delivered must be accompanied by a certificate containing the following information:

- Name of supplier
- Type and grade of concrete
- Mix code number
- Time and date of mixing
- Temperature of mixing
- Additives
- Cement type
- Cement content
- Water cement ratio or quantity of added water
- Time of arrival of truck on site
- Time of end of discharge
- Registration number of truck
- Delivery certificate number

The certificates shall be available to the Engineer for quality supervision.

Any addition of water and admixtures to the concrete after the concrete has been discharged from the mixing plant shall not be accepted.

5.3.3 CONCRETING PROCEDURE

The concrete workability shall remain satisfactory until placing and compaction is finished. This shall at a minimum be 3 hours at 25°C upon arrival on site, this shall also be true for hot weather periods.

During cold weather and frost periods, the concrete shall be placed at a specified minimum temperature because of the lower hardening rate and the danger of permanent impairment of defined concrete properties. With ambient temperatures of +5°C to -3°C, the concrete temperature upon placing must not fall below +5°C. With ambient temperatures below -3°C, the concrete temperature must not fall below +10°C.
During hardening, the concrete temperature may not exceed 50°C.

Before the concrete is placed, all formwork elements and surfaces to come into contact with the concrete shall be cleaned from dust, mud and other impurities. The concrete shall not be placed in standing water unless this has been specified or approved.

During placing, suitable means shall be provided to prevent premature hardening of the concrete put in contact with hot surfaces.

When placing concrete in layers, if no construction joints are foreseen, the placing may only be interrupted for a period of time during which the concrete does not set, so that a good and even connection is possible between the two layers of concrete. The concrete shall be placed in layers of such depth that the new layer will be readily and properly mixed with the previous layer below by the use of vibrators. The difference in height of the layer's level on the right hand sidewall and the left hand sidewall of the final lining may not exceed 1 m.

Concreting shall begin in the bottom parts of the sidewalls and shall finish in the crown. Normally the concrete shall be pressed into the formwork. If the formwork is filled by gravity flow, the concrete's height of fall shall not exceed 1 m.

The type and number of vibrators shall be approved by the Engineer and shall consider the mass and quality of concrete to be compacted and the type of formwork.

The formwork shall be released, when the final concrete lining meets its release strength, measured in the crown by suitable means of measurement.

5.3.4 CURING

The curing of the final lining surface will start immediately after the formwork is released.

When water curing is applied, chill shocks are to be avoided (as could occur when cool water comes into contact with warm concrete surfaces) due to the resulting danger of peeling or scaling. The quality of water used for curing shall be the same as that used for concrete mixing. If liquid membranes are used, they must not affect the normal setting reaction of cement. Compounds incorporating reflective, white or light-coloured pigments shall be used.
The methods of preventing the concrete from prematurely drying are to be submitted to the Engineer for approval before use.

The concrete must be cured during the first four days.

6. Quality Control

All components must have a valid quality certificate and a valid permission for the intended use.

During the entire period of construction, the Contractor will have to verify the material properties and qualities as defined by the Specifications and Standards.

In addition to the tests and investigations contained in the Specifications and Standards, all other tests deemed necessary by the Engineer are to be performed.

Records are to be kept of all test results and submitted to the Engineer. The Contractor shall grant the Engineer full access to and use of the laboratory and shall produce on demand the records of all tests carried out.

6.1 Suitability Tests

6.1.1 CONCRETE COMPONENTS

No aggregates shall be delivered to the site without satisfactory initial sampling and testing. The sample of fine aggregate shall be 25kg in weight and that of the coarse aggregate shall be 50kg in weight.

The Contractor's attention is drawn to the need to maintain a consistent aggregate quality and he will be expected to undertake adequate testing to ensure that the quality does not vary significantly (reference is made to Subchapter 6.2, Quality Control Tests).

All components have to be certificated for their origin and quality. The suitability of the components used has to be approved by the Contractor's concrete expert and by the Engineer.
6.1.2 CONCRETE

In order to verify the suitability of the concrete compositions for the respective task, tests at the site or the mixing plant have to be carried out for both designed concrete compositions (winter and summer composition). The following items have to be tested using three samples per item under the mentioned conditions:

- Bulk density
- Air void content (= 3% to 6 %, maximum)
- Consistency immediately after mixing and one hour later (= class F3; DIN 1045–2)
- Release strength after 12 hours (= 3 MPa)
- Characteristic strength after 28 days (= 35 MPa)
- Characteristic strength after 90 days

6.2 Quality Control Tests

6.2.1 AGGREGATES

The following tests have to be carried out with a frequency of “each delivery”

- grading analyses
- wet analyses
- moisture content, for sand
- organic impurities
- visual inspections of aggregate type, granulometric composition, aggregate condition, particle shape, detrimental components (e.g. coal, humic substances, brittle grains, etc.)

The moisture content of the sand is to be checked in addition once a week.

Chloride and sulphate tests have to be carried out once each 4 months and in case of suspected change.

The tests are to be carried out in accordance with DIN EN 12620.
6.2.2 CEMENT AND CEMENTING MATERIALS

The following tests have to be carried out every 4 months:

- compressive strength
- specific surface
- chemical analysis.

Certificates issued by the supplier shall be tested per storage vessel.

The tests are to be conducted in accordance with the German DIN EN 196 Standard and the requirements of Subchapter 2, Materials.

6.2.3 ADMIXTURES

The certificates issued by the supplier have to be checked at each delivery to the site.

6.2.4 CONCRETE

Fresh concrete has to be tested according to the criteria listed below:

<table>
<thead>
<tr>
<th>testing item</th>
<th>testing frequency</th>
<th>testing procedure</th>
<th>testing moment</th>
</tr>
</thead>
<tbody>
<tr>
<td>consistency</td>
<td>once for every batch on site</td>
<td>acc. to German DIN EN 12350 Standard</td>
<td>before placing of concrete</td>
</tr>
<tr>
<td>water / cement ratio</td>
<td>once for every batch on site</td>
<td>by visual inspection</td>
<td>before placing of concrete</td>
</tr>
<tr>
<td>unit weight</td>
<td>once for every batch on site</td>
<td>by visual inspection</td>
<td>before placing of concrete</td>
</tr>
<tr>
<td>bulk density</td>
<td>three times per concrete bay</td>
<td>acc. to German DIN EN 12350 Standard</td>
<td>during concreting</td>
</tr>
<tr>
<td>air void content</td>
<td>three times per concrete bay</td>
<td>acc. to German DIN EN 12350 Standard</td>
<td>during concreting</td>
</tr>
</tbody>
</table>

Hardened concrete has to be tested according to the criteria listed below:
### Technical Specification

### Concrete Works Final Lining

<table>
<thead>
<tr>
<th>testing item</th>
<th>testing frequency</th>
<th>testing procedure</th>
<th>testing moment</th>
</tr>
</thead>
<tbody>
<tr>
<td>compressive strength</td>
<td>three times per concrete bay at the crown</td>
<td>with penetration test or pendulum hammer</td>
<td>after 12 h (release strength)</td>
</tr>
<tr>

<td>three cubes or cylinders per concrete bay</td>
<td>acc. to German DIN EN 12390 Standard</td>
<td>after 28 days (characteristic strength)</td>
</tr>
<tr>
<td>compressive strength</td>
<td>three cubes or cylinders per concrete bay</td>
<td>acc. to German DIN EN 12390 Standard</td>
<td>after 90 days (characteristic strength)</td>
</tr>
<tr>
<td>air void content</td>
<td>three times per concrete bay</td>
<td>acc. to German DIN EN 12390 Standard</td>
<td>after 7 days (abrasion resistance)</td>
</tr>
</tbody>
</table>

The testing procedure and interpretation of results is described in the above mentioned references. The limit values of the individual tests are specified in Subchapter 2, Materials and Subchapter 6.1, Suitability Tests.

#### 6.2.5 CONCRETE WORKS

The minimum radius of the cross-section shall be the design radius. Smaller radii are to be avoided.

If faced with a smaller radius, the following measures will have to be taken:

<table>
<thead>
<tr>
<th>origin</th>
<th>extension</th>
<th>consequence</th>
<th>check</th>
<th>measures</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local “breakdown” of formwork</td>
<td>limited in size</td>
<td>increase of concrete lining thickness</td>
<td>sufficient thickness of concrete lining and sufficient flow volume of cross section</td>
<td>grinding of bulges</td>
</tr>
<tr>
<td></td>
<td>whole concrete bay</td>
<td></td>
<td></td>
<td>if maximum flow cannot be achieved, breakdown and reconstruction of</td>
</tr>
</tbody>
</table>
Technical Specification
Concrete Works Final Lining

<table>
<thead>
<tr>
<th>wrong alignment of formwork</th>
<th>whole concrete bay</th>
<th>increase / decrease of concrete lining thickness</th>
<th>sufficient thickness of concrete lining</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>if maximum flow can not be achieved, breakdown and reconstruction of concrete bay in any other case, smoothening of the surface as described below</td>
</tr>
</tbody>
</table>

The minimum thickness of the final concrete lining shall be the design thickness. Any reduction in thickness shall be avoided. Any increase in thickness shall be limited to the design thickness + 10 cm. The space, available for the placing of the final concrete lining has to be proven by survey of the shotcrete lining surface.

Should the required limits not be met (thinner final lining), the area in question should be re-excavated and re-supported. Should the limits be exceeded, the difference between the allowable and the measured thickness shall be compensated by additional shotcrete.

The survey results of the shotcrete surface, as well as the measures to be taken when the limits are exceeded are – in any case – subject to Engineer’s approval.

The final concrete lining surface shall be smooth and flat. Wedges and bulges are to be avoided, or smoothened by grinding. Unevenness shall not exceed 4 degrees (angle of gradient) in all directions.

7. Measurements

The quantity survey unit of the concrete for the final lining shall be m³.
8. Acceptance

8.1 Conformity of Work with Design and Technical Specification

The works shall be carried out in accordance with the design, the Technical Specification(s) and the written instructions of the Engineer.

8.2 Acceptance of Works To Be Removed or Covered

8.2.1 DOCUMENTS AND DATA

The acceptance of works which are to be removed or covered shall be based upon:
- a written statement by the Engineer entered into the Site Book that the works have been executed in accordance with the design and the Technical Specification(s),
- other written statements by the Engineer commenting on the execution of the works.

8.2.2 SCOPE OF WORKS

The scope of works to be removed or covered shall be determined by written statements of the Engineer and by other documents confirmed by the Engineer.

Technical Specification
Concrete Works Invert Segment

1. Introduction

1.1 Subject of Technical Specification
This Technical Specification (TS) shall define the requirements for the execution and commissioning of the invert segment as part of the final tunnel lining for the Diversion Tunnel at the Niagara Tunnel Facility Project.

1.2 Range of Technical Specification Application
This TS is a bid and contract document used for the execution and commissioning of the works referred to in Item 1.1.

The provisions contained in this Specification refer to the working methods to be adopted for the:

a) delivery of all the components and the entire equipment required to the site
b) installation of a plant on site for the prefabrication of the invert segment with the entire equipment required for production and testing
c) production of invert segments, storage and delivery on site
d) installation of invert segments on site
e) quality control for workmanship and materials.

The Scope of Work is defined for the Diversion Tunnel during the construction of the final lining.

1.3 Definitions
The basic definitions given in this TS are in conformity with the relevant standards in force.

1.3.1 INVERT SEGMENT CONCRETE
For the concrete composition, Canadian standards shall mainly be applicable. A concrete with high abrasion resistance shall be produced.

The invert segments will be prefabricated in a plant on site. The dimensions of the prefabricated invert segments have been documented in the corresponding drawings.
1.3.2 FORMWORK

Sufficient formwork moulds will have to be supplied for the production of the prefabricated invert segment. Steel formwork with a smooth surface shall be used. The formwork moulds shall be equipped with enough vibrators for concrete compacting.

Both, formwork and formwork joints will have to be completely tight to prevent leakage of grouting material. Both, formwork joints and formwork skin joints will have to be spaced at regular intervals.

The formwork is be thoroughly cleaned before use.

Any formwork support material subject to rust or corrosion is to be removed upon striking of the formwork. Any reinforcement or support material, remaining in the concrete and coming into contact with atmospheric humidity is to be rust and corrosion-proof.

All proposed shuttering details are to be submitted for approval by the Engineer.

The formwork system in general is subject to the Engineer’s approval.

1.3.3 JOINTS

All joints are to be butt joints and placed according to the drawings.

Due to the tunnel alignment and the straight course of the invert segment, there will be an offset within the joints in the curves. The offset size should be minimized readjustment and shall not exceed the maximum theoretical value.

1.3.4 CURING

Until the concrete is sufficiently hardened, it is to be protected against detrimental influences - for example excessive warming, drying out due to sun or wind, running water, chemical attack, frost.

1.3.5 PROTECTION SHEET

In order to protect the waterproofing membrane system against damage, a geotextile with an area weight of $\geq 750$ g / m$^2$ shall be laid upon the waterproofing membrane prior to the installation of the precast invert segments.
1.3.6 MORTAR BEDDING

The precast invert segments shall be embedded in a mortar bed. The mortar bed shall be provided before the invert segments are installed. The mortar bed shall stabilize the invert segment in its exact position. The thickness shall depend on the surrounding conditions, but shall not exceed 5 cm.

1.3.7 CONTACT GROUTING

Upon installation of the invert segment, there might be a few porous cavities in the mortar bed, caused by the installation procedure. These cavities will have to be filled with grout. For this task to be accomplished, three holes with a diameter of 50 mm are provided in every invert segment.

1.3.8 INTERFACE GROUTING

For a pre-stressing of the final concrete lining, high-pressure grouting at the interface of the waterproofing system and the shotcrete lining will be carried out. For this task, a separate specification is available.

1.4 General Work Requirements

The Contractor shall be responsible for the quality of material and workmanship and for their conformity with the Design Documentation, other corresponding Specifications and Method Statements and the Engineer’s instructions.

The Contractor shall provide his personnel with the know-how and equipment necessary in accordance with the Specification and shall grant them access to the works to enable them to carry out their work in a safe and proper way.

Before commencing the concrete works, the Contractor shall propose a concept for these works. The concept shall comprise the equipment envisaged, the scope of work and the work stages.
2. Materials

2.1 Aggregates

Aggregates shall be taken from a source approved by the Engineer. The mixture of the aggregates shall be uniform without gap grading. The gravel (coarse) fraction shall be of cubic crushed or rounded form.

Aggregates shall be hard, durable, non-porous and clean and shall not be chemically reactive. They shall not contain any deleterious material in sufficient quantity to adversely affect the strength at any age or the durability of the concrete or to cause corrosion of reinforcement.

The grading and the shape of the aggregates shall be such that a concrete can be produced with the specified proportions and consistency, which will readily work into position without segregation and without the use of excessive water and which can readily be compacted into a dense impervious mass.

The nominal maximum aggregate size shall be 16 mm. The gravel fraction of the aggregate shall not exhibit excessive fragmentation during delivery. The percentage of brittle grains shall be less than 5%. The percentage of particles smaller than 0.06 mm, which can be washed away, shall not exceed 1%.

Sand and gravel shall be clean. Frozen aggregates shall not be used. The minimum permissible temperature shall be +3°C. Should the aggregates be warmed using steam, special attention shall be paid to controlling the moisture content, particularly in the sand fraction.

All aggregates shall have a specific gravity of not less than 26 kN/m³.

The grading curve shall comply with the curve determined during suitability tests. The deviation of the given specified gradation should not exceed the values listed below.

<table>
<thead>
<tr>
<th>Grain Diameter</th>
<th>Admissible Deviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.06 mm</td>
<td>−/+ 1%</td>
</tr>
</tbody>
</table>
2.2 Cement and Cementing Materials

It is of particular importance to use cement of uniform chemical composition and uniform fineness. Before commencement of delivery, the required characteristic values are to be agreed upon by the Engineer with the cement manufacturer. For the entire cement delivered, the manufacturer shall make the cement analyses and the standard tests results available.

Cement shall be Ordinary Portland Cement, Rapid Hardening Portland Cement or Portland Pulverized Fuel Ash Cement. The cement type shall be 20 according to the C.S.A. Standard 23.1–00.

In addition, the cement used should satisfy the following requirements:

(a) Initial setting time not less than three hours.

(b) Fineness: Not less than 340 m²/kg; if content of pulverized–fuel ash greater than 20 %, not less than 380 m²/kg.

(c) Bleeding: not more than 20 cm³ (Heidelberg Method); if content of pulverized fuel ash greater than 20 %, not more than 15 cm³.

(d) Compressive strength after one day (24 h ± 1 h) on mortar cubes: not less than 9 N/mm²

(e) The temperature of the cement at the time of use in the mixing plant must not be higher than 60°C.

If cementing materials (like fly ash) are used, their suitability to meet the special requirements of the final concrete lining will have to be tested and the results will have to be approved by the Engineer.

2.3 Water

The water shall be clean and free of harmful matter in such quantities, as would affect the properties of concrete in the plastic or hardened state.

The water shall satisfy the requirements of potable water.
2.4 Admixtures

Admixtures added to the concrete, must not affect the concrete’s hardening, strength and durability or cause corrosion of the reinforcement.

Chlorides or materials containing chlorides which promote steel corrosion may not be added to reinforced concrete or concrete which comes into contact with reinforced concrete. The prerequisite for the use of admixtures is a qualification test to be performed by the Contractor. The test results must be submitted to the Engineer.

2.5 Concrete

The concrete mix design should meet the following requirements (according to C.S.A 23.1–00):

- concrete with high abrasion resistance
- water / cement ratio \( \leq 0.45 \)
- aggregates size 0 mm to 16 mm
- recommended cement volume 300 kg / m³
- required characteristic strength 35 MPa after 28 days
- air void content 3% to 6% at a maximum

2.6 Reinforcement

The reinforcement steel used, shall be ribbed steel, grade 500 R or 500 W according to C.S.A. Standard 23.1–00.

In order to improve the composite action and to limit the crack formation, small-diameter reinforcement bars with a small spacing shall be used.

The concrete cover shall be sufficient in accordance with the invert segment requirements and in compliance with the design. The sufficient concrete cover shall be ensured by concrete spacers, fixed to the reinforcement in sufficient number.

2.7 Mortar

The mortar for the mortar bedding shall be composed of one part of cement and three parts of sand. The cement shall fulfill the above mentioned requirements. The
sand shall consist of naturally occurring sand, of crushed rock or of gravel or a combination thereof. The sand shall be clean, hard and free of impurities. It shall comply with the above mentioned concrete aggregate requirements.

Mortar plasticizer, if used, shall be subject to acceptance by the Engineer and shall be used in the proportions and manner recommended by the manufacturer.

The water content of mortar shall be just sufficient to ensure a dense mortar with adequate workability, when trowelled or worked into place. Mortar that has begun to harden shall not be used in any part of the works.

All materials shall be accurately gauged by gauge boxes and mechanically mixed and used within 30 minutes of first mixing. Retempering of mortar will not be permitted. Gauge boxes and mixers shall be kept clean.

2.8 Contact Grouting Material

The contact grouting material shall be a cement–water suspension with sufficient fluid characteristics to fill the porous cavities and annular space between the invert segment and the mortar bedding.

If other materials are used, they have to be consistent with the concrete. The consistency has to be demonstrated by tests or approved documents and the use of alternative materials has to be approved by the Engineer.

3. Equipment

The works may be performed using any type of equipment approved by the Engineer.

The entire equipment must have a valid quality control certificate and is to be inspected within regular inspection periods.

The design and construction of the formwork moulds is to be evaluated by approved documents (calculations and drawings) and the moulds are to be checked by a Professional Engineer. The results are to be certificated by the Engineer.
4. Transport

All components shall be transported by suitable means of transport and in accordance with industrial safety and road traffic regulations to avoid any damage.

The concrete must not separate while being transported to the construction site and it shall be of the required workability at the location and time of placing.

The precast invert segments have to be loaded, unloaded and carried on site in such a way, that they and especially their wedges are protected against damage at every time and that these procedures will not cause loading conditions, which are not covered by the calculations and the design.

5. Workmanship

5.1 General

Before starting the concreting works, the Contractor shall develop a concrete works program, which shall contain information on the

- type of concrete production, on site, ready mix
- distance of external plants to the site
- capacity of the mixing plants, additional plants for substitution (incl. distance to the site)
- testing procedure, suitability tests, quality control tests
- thermal development of the concrete during hardening
- schedule of concreting, simultaneous concreting
- concrete works procedure - use and preparation of formwork, cast in place procedure (progress, vibration, quality supervision)
- formwork replacement (concrete requirements)
- curing procedure

The concrete works program has to be submitted to the Engineer for approval.
5.2 Formwork

The formwork has to be erected and stabilized in such a way that all stresses and strains caused by the concrete works can be covered.

Special attention is to be paid to the sealing of joints and the concreting of windows. The concrete surface must be smooth, free of voids and pores. Any formwork use more than once must be approved by the Engineer.

The construction element may only be stripped and the support may only be removed when the concrete has sufficiently hardened. The concrete has sufficiently hardened when the element is strong enough to support all loads, to which it is subjected when stripped, with the prescribed safety.

Before concreting, appropriate shutter oil is to be applied to ensure that no concrete will stick to the formwork.

Generally, the formwork system (incl. skin) is subject to the Engineer’s approval.

5.3 Concrete Works

5.3.1 CONCRETE PRODUCTION, SITE MIXING PLANT

The aggregates have to be stored on site in separate boxes for gravel, coarse sand and fine aggregates. They have to be protected against dryness, wetness and freezing. For the production of all types of concrete the individual aggregate components are to be measured by weight using automatic dosing equipment.

The cement and the additives shall be stored in such way that they will be protected against seasonal influences and that they will keep their original state of quality at the time of delivery. For the concrete production, the components are to be measured by weight, using automatic dosing equipment.

The concrete mixing plant is to be laid out for a separated and automatic batching of 3 different additives. To permit monitoring of the levels of additives added to the concrete mixture, a transparent gauge glass is to be foreseen.

The concrete components (cement, aggregates, water and additives) must be measured with an accuracy of 3 %. The weight batching machines shall be carefully maintained and cleaned and provided with simple and convenient means of checking the weighing mechanisms plus they shall be checked when required by the Engineer.
The composition of each type of concrete to be mixed is to be posted at the mixing plant in a clearly legible form and must include the requirements of the given standards. The materials must be mixed in concrete mixers which are suitable for the pertinent concrete composition. The concrete mixer must be equipped with an electrical current indicator to facilitate regulation of the concrete's consistency. If the specific water content of the aggregates varies, the amount of wet material plus the amount of mixing water must always be selected in such a way, that the total amount of water remains constant.

The dimensions of the mixing plant have to be sufficient to deliver enough concrete to all relevant sites at any time of the concreting process. All concrete components and the concrete production have to be protected from extreme weather conditions (heat, rain). Mixing plants for sites located in cold weather areas, which may experience frost periods, are to be equipped with mixing water and aggregate heating systems.

A site laboratory, fully equipped to carry out all concrete and concrete component tests required, is to be set up and operated by experienced personnel. An expert in concrete technology and concrete production shall be in charge of this laboratory.

Test mixes are to be made for each type of concrete. The results are to be submitted to the Engineer. The mixes shall be approved by the Engineer and a trial mix shall be prepared under full-scale conditions, including workability tests and cube testing.

5.3.2 READY-MIXED CONCRETE

The entire ready-mixed concrete shall meet the requirements described in this Specification. In addition to this, the Contractor shall submit the name and address of the ready-mix Contractor to the Engineer for approval, giving all operation and plant details.

The details of the ready-mix Contractor shall include information on the plant, the equipment, the storage depots, as well as the transportation and quality systems. The Engineer shall have access to the ready-mix site for inspection at any time. The Engineer may reject the proposed ready-mix Contractor and may cancel an approval at any time, if the quality of the concrete or the documentation of the quality control is not satisfactory in the opinion of the Engineer.

All testing preparation and testing of the mixed concrete shall be executed on site.
The Contractor shall ensure that the supplier keeps records of all the required tests and the quality control for mixing and transportation.

The concrete shall be delivered to the site in truck mixers or agitators which are continuously in operation. Each batch delivered must be accompanied by a certificate containing the following information:

- Name of supplier
- Type and grade of concrete
- Mix code number
- Time and date of mixing
- Temperature of mixing
- Additives
- Cement type
- Cement content
- Water cement ratio or quantity of added water
- Time of arrival of truck on site
- Time of end of discharge
- Registration number of truck
- Delivery certificate number

The certificates shall be available to the Engineer for quality supervision.

Any addition of water and admixtures to the concrete after the concrete has been discharged from the mixing plant shall not be accepted.

5.3.3 CONCRETING PROCEDURE

The concreting procedure will start once the required reinforcement has been arranged and fixed against displacement during concreting. The formwork and the reinforcement arrangement will have to be checked for compliance with the requirements of the Contractor’s Quality Management System. The approval has to be recorded and made available for the Engineer’s quality supervision.

The concrete workability shall remain satisfactory until placing and compaction is finished. This shall at a minimum be 3 hours at 25°C upon arrival on site, this shall also be true for hot weather periods.

During cold weather and frost periods the concrete shall be placed at a specified minimum temperature because of the lower hardening rate and the danger of permanent impairment of defined concrete properties. With ambient temperatures of
+5°C to -3°C, the concrete temperature upon placing must not fall below +5°C. With ambient temperatures below -3°C, the concrete temperature must not fall below +10°C.

During hardening, the concrete temperature may not exceed 50°C.

Before the concrete is placed, all formwork elements and surfaces to come into contact with the concrete shall be cleaned from dust, mud and other impurities. The concrete shall not be placed in standing water unless this has been specified or approved.

During placing, suitable means shall be provided to prevent premature hardening of the concrete put in contact with hot surfaces.

When placing concrete in layers, if no construction joints are foreseen, the placing may only be interrupted for such a period of time during which the concrete does not set, so that a good and even connection is possible between the two layers of concrete. The concrete shall be placed in level layers of such depth that the new layer will be readily and properly mixed with the previous layer below by the use of internal vibrators.

The type and number of vibrators shall be approved by the Engineer and shall consider the mass of concrete to be compacted, the density of reinforcement, and the type of formwork.

The formwork shall be released, when the invert segments meet the required strength. The required strength shall be calculated and the corresponding period shall be verified by suitability tests.

5.3.4 CURING

The invert segment will be kept in the formwork until the required release strength for the formwork is reached. The curing measures for the surface, which is not covered by formwork, have to be started immediately after concreting is finished.

When water curing is applied, chill shocks are to be avoided (as could occur when cool water comes into contact with warm concrete surfaces) due to the resulting danger of peeling, or scaling. The quality of water used for curing shall be the same as that used for concrete mixing. If liquid membranes are used, they must not affect the normal setting reaction of cement. Compounds incorporating reflective, white or light-coloured pigments shall be used.
The concrete has to be cured until the formwork is released.

5.3.5 STORAGE

The prefabricated invert segments are to be stored in a way protecting them against any kind of damage. To minimize internal stress and strain conditions during storage, they have to be supported by wooden line bearers, arranged in the third points of the curved part.

6. Quality Control

All components must have a valid quality certificate and a valid permission for the intended use.

During the entire period of construction, the Contractor will have to verify the material properties and qualities as defined by the Specifications and Standards.

In addition to the tests and investigations contained in the Specifications and Standards, all other tests deemed necessary by the Engineer are to be performed.

Records are to be kept of all test results and submitted to the Engineer. The Contractor shall grant the Engineer full access to and use of the laboratory and shall produce on demand the records of all tests carried out.

6.1 Suitability Tests

6.1.1 CONCRETE COMPONENTS

No aggregates shall be delivered to the site without satisfactory initial sampling and testing. The sample of fine aggregate shall be 25kg in weight and that of the coarse aggregate shall be 50kg in weight.

The Contractor's attention is drawn to the need to maintain a consistent aggregate quality and he will be expected to undertake adequate testing to ensure that the quality does not vary significantly (reference is made to Subchapter 6.2, Quality Control Tests).
Technical Specification

Concrete Works Invert Segment

All components have to be certificated for their origin and quality. The suitability of the components used has to be approved by the Contractor’s concrete expert and by the Engineer.

6.1.2 CONCRETE

In order to verify the suitability of the concrete compositions for the respective tasks, tests at the site or at the mixing plant have to be carried out for both designed concrete compositions (winter and summer composition). The following items have to be tested using three samples per item under the mentioned conditions:

- Bulk density
- Air void content (= 3% to 6%, maximum)
- Consistency immediately after mixing and one hour later (= class F3; DIN 1045–2)
- Characteristic strength after 28 days (= 35 MPa)

6.1.3 MOMENT OF FORMWORK RELEASE

The required concrete strength has to be calculated, considering all loading conditions of the invert segment during the hardening period.

The moment of formwork release has to be determined by concrete strength tests after 3 days, 7 days and 28 days. The tests have to be carried out using three samples per test. The required strength and the corresponding moment have to be analyzed by interpretation of the test results.

6.2 Quality Control Tests

6.2.1 AGGREGATES

The following tests have to be carried out with a frequency of “each delivery”

- grading analyses
- wet analyses
- moisture content, for sand
- organic impurities
• visual inspection of aggregate type, granulometric composition, aggregate condition, particle shape, detrimental components (e.g. coal, humic substances, brittle grains, etc.)

The moisture content of the sand is to be checked in addition once a week.

Chloride and sulphate tests have to be carried out once each 4 months and in case of suspected change.

The tests are to be carried out in accordance with DIN EN 12620.

6.2.2 CEMENT AND CEMENTING MATERIALS

The following tests have to be carried out every 4 months:

• compressive strength
• specific surface
• chemical analysis.

Certificates issued by the supplier shall be tested per storage vessel.

The tests are to be conducted in accordance with the German DIN EN 196 Standard and the requirements of Subchapter 2, Materials.

6.2.3 ADMIXTURES

The certificates issued by the supplier have to be checked at each delivery to the site.

6.2.4 CONCRETE

Fresh concrete has to be tested according to the criteria listed below:

<table>
<thead>
<tr>
<th>testing item</th>
<th>testing frequency</th>
<th>testing procedure</th>
<th>testing moment</th>
</tr>
</thead>
<tbody>
<tr>
<td>consistency</td>
<td>once for every batch on site</td>

</tr>
<tr>
<td>air void content</td>
<td>three times per invert segment</td>
<td>acc. to German DIN EN 12390 Standard</td>
<td>after 7 days (abrasion resistance)</td>
</tr>
</tbody>
</table>

The testing procedure and interpretation of results is described in the above mentioned references. The limit values of the individual tests are specified in Subchapter 2, Materials and Subchapter 6.1, Suitability Tests.

6.2.5 CONCRETE WORKS

The minimum thickness of the final concrete lining shall be the design thickness. Any reduction in thickness shall be avoided. Any increase in thickness shall be limited to the design thickness + 10 cm. Tolerances in extension, length, width, shall not exceed 10% of the original (design) dimensions.

Should the required limits not be met (thinner invert segment), the related segment will have to be built a second time.

The final lining surface of the installed segments shall be smooth and flat. Wedges and burrs are to be avoided, or smoothened by grinding. Unevenness shall not exceed 4 degrees (angle of gradient) in all directions.
7. **Measurements**

The quantity survey units may be described as follows

- concrete for invert segment  = \( m^3 \)
- reinforcement  = ton
- mortar for mortar bedding  = \( m^2 \)
- protective sheet  = \( m^2 \)

8. **Acceptance**

8.1 **Conformity of Work with Design and Technical Specification**

The works shall be carried out in accordance with the design, the Technical Specification(s) and the written instructions of the Engineer.

8.2 **Acceptance of Works To Be Removed or Covered**

8.2.1 **DOCUMENTS AND DATA**

The acceptance of works which are to be removed or covered shall be based upon:

- a written statement by the Engineer entered into the Site Book that the works have been executed in accordance with the design and the Technical Specification(s),
- other written statements by the Engineer commenting on the execution of the works.

8.2.2 **SCOPE OF WORKS**

The scope of works to be removed or covered shall be determined by written statements of the Engineer and by other documents confirmed by the Engineer.

1. **Introduction**

1.1 **Subject of Technical Specification**

This Technical Specification (TS) shall define the requirements for the execution and commissioning of the concrete works for the intake and outlet structures at the Niagara Tunnel Facility Project.

1.2 **Range of Technical Specification Application**

This TS is a bid and contract document used for the execution and commissioning of the works referred to in Item 1.1.

The provisions contained in this Specification refer to the working methods to be adopted for the:

a) delivery of all the components and the equipment required to the site
b) installation of required formwork
c) execution of concrete works
d) quality control for workmanship and material.

The Scope of Work is defined for the concreting of the intake and outlet structures.

1.3 **Definitions**

The basic definitions given in this TS are in conformity with the relevant standards in force.

1.3.1 **OUTLET STRUCTURE**

The outlet structure shall be built in a watertight manner concerning both concrete composition and construction.

In addition to these requirements, the concrete composition shall meet the C.S.A. requirements for resistance against thawing and freezing.

1.3.2 **INTAKE STRUCTURE**

The intake structure shall be built in a watertight manner concerning both concrete composition and construction.

In addition to these requirements, the concrete composition shall meet the C.S.A. requirements for resistance against thawing and freezing, as well as the requirements for resistance against severe sulphate attack.

1.3.3 **CONCRETE SUBBASE**

The concrete subbase is a layer of lean concrete, arranged beneath the invert of the structure. It serves the task of leveling the excavated underground surface and of allowing an exact and
proportion arrangement of the required reinforcement. It moreover ensures a continuous bedding of the structure’s invert.

The thickness of the subbase concrete shall not exceed 10 cm on average.

1.3.4 CONCRETE FILL

The concrete fill is a lean concrete layer, placed on the bottom of the canal to protect the Rochester Shale surface and to level out the invert of the canal. The minimum thickness of the concrete fill shall be 5 cm.

1.3.5 1ST STAGE INVERT CONCRETE

The 1st stage invert concrete is part of the final structure and shall be watertight. It shall be installed immediately after excavation. It shall take on the loads caused by the installation and the launching of the Tunnel Boring Machine (TBM). The 1st stage invert concrete shall be reinforced concrete in accordance with the design requirements.

1.3.6 2ND STAGE INVERT CONCRETE

The 2nd stage invert concrete serves the completion of the invert within the shaft structure to the final invert level. The 2nd stage invert concrete shall meet the requirements with respect to surface evenness and smoothness stipulated by the flow criteria. The 2nd stage invert concrete shall be watertight and shall consist of reinforced concrete in accordance with the design requirements.

1.3.7 CAST-IN-PLACE CONCRETE

Cast-in-place concrete specifies the other parts of the structure (shaft walls, linings of cross-sections) which are not described above. It will be placed upon completion of the excavation and support period of the Diversion Tunnel. The cast-in-place concrete shall meet the requirements with respect to surface evenness and smoothness stipulated by the flow criteria. The cast-in-place concrete shall be watertight and shall consist of reinforced concrete in accordance with the design requirements.

1.3.8 FORMWORK

Formwork with a smooth surface shall be used. Special attention is to be paid to the sealing of joints and concreting windows. The shutter length (= formwork construction length) should be in the range of 5 m.

Both, formwork and formwork joints will have to be completely tight to prevent the leakage of grout material. Both formwork joints and formwork skin joints will have to be spaced at regular intervals.

Preference is given to steel formwork. Wooden formwork may not be exposed to the sun and to wind for excessive periods of time. The formwork shall be fixed on a shutter which is designed to the requirements of the concreting procedure.

Within the formwork skin, windows and hoses for concreting behind the formwork shall be provided in sufficient number and in a way ensuring a sufficient filling of the concrete bay under all project conditions.

The formwork system in general is subject to the Engineer’s approval.
1.3.9 JOINTS

All joints shall be butt joints and placed according to the drawings. Every joint, expansion joint and construction joint shall be sealed with a corresponding joint tape in compliance with the Specification for the waterproofing system.

1.3.10 CURING

Until the concrete is sufficiently hardened, it is to be protected against detrimental influences – for example excessive warming, drying out due to sun or wind, running water, chemical attack.

1.3.11 CONTACT GROUTING

Upon setting of the concrete, there will be a few porous cavities especially in the crown of the tunnel. In order to ensure a homogenous bedding of the structure, these cavities will have to be filled with grout.

For this task to be accomplished, holes shall be arranged in the crown area’s concrete lining.

1.3.12 COMPRESSIBLE MATERIAL LAYER

In order to limit the total final loads exerted on the structures by eliminating the loadings caused by long-term underground pressure rearrangement, a layer of compressible material, with a thickness of 10 cm, shall be foreseen between the structure’s backside and the excavation surface.

1.4 General Work Requirements

The Contractor shall be responsible for the quality of material and workmanship and for their conformity with the Design Documentation, other corresponding Specifications and Method Statements and the Engineer’s instructions.

The Contractor shall provide his personnel with the know-how and equipment necessary in accordance with the Specification and shall grant them access to the works to enable them to carry out their work in a safe and proper way.

Before commencing the concrete works, the Contractor shall propose a concept for these works. The concept shall comprise the equipment envisaged, the scope of work and the work stages.

2. Materials

2.1 Aggregates

Aggregates shall be taken from a source approved by the Engineer. The mixture of the aggregates shall be uniform without gap grading. The gravel (coarse) fraction shall be of cubic crushed or rounded form.
Aggregates shall be hard, durable, non-porous and clean and shall not be chemically reactive. They shall not contain any deleterious material in sufficient quantity to adversely affect the strength at any age or the durability of the concrete or to cause corrosion of reinforcement.

The grading and the shape of the aggregates shall be such that a concrete can be produced with the specified proportions and consistency, which will readily work into position without segregation and without the use of excessive water and which can readily be compacted into a dense impervious mass.

The nominal maximum aggregate size shall be 32 mm. The gravel fraction of the aggregate shall not exhibit excessive fragmentation during delivery. The percentage of brittle grains shall be less than 5%. The percentage of particles smaller than 0.06 mm, which can be washed away, shall not exceed 1%.

Sand and gravel shall be clean. Frozen aggregates shall not be used. The minimum permissible temperature shall be + 3°C. Should the aggregates be warmed using steam, special attention shall be paid to controlling the moisture content, particularly in the sand fraction.

All aggregates shall have a specific gravity of not less than 26 kN/m³.

The grading curve shall comply with the curve determined during suitability tests. The deviation of the given specified gradation shall not exceed the values listed below.

<table>
<thead>
<tr>
<th>Grain Diameter</th>
<th>Admissible Deviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.06 mm</td>
<td>+/- 1 %</td>
</tr>
<tr>
<td>0.25 mm</td>
<td>+/- 1 %</td>
</tr>
<tr>
<td>1 mm</td>
<td>+/- 2 %</td>
</tr>
<tr>
<td>4 mm</td>
<td>+/- 3 %</td>
</tr>
</tbody>
</table>

### 2.2 Cement and Cementing Materials

It is of particular importance to use cement of uniform chemical composition and uniform fineness. Before commencement of delivery, the required characteristic values are to be agreed upon by the Engineer with the cement manufacturer. For the entire cement delivered, the manufacturer shall make the cement analyses and the standard test results available.

The cement shall be ordinary Portland cement, rapid hardening Portland cement or Portland pulverized fuel ash cement. The cement type shall be 20 according to the C.S.A. Standard 23.1-00.

In addition, the cement used shall satisfy the following requirements:

(a) Initial setting time not less than three hours.
(b) Fineness: Not less than 340 m²/kg; if content of pulverized fuel ash greater than 20 %, not less than 380 m²/kg.

(c) Bleeding: not more than 20 cm³ (Heidelberg Method); if content of pulverized fuel ash greater than 20 %, not more than 15 cm³.

(d) Compressive strength after one day (24 h ± 1 h) on mortar cubes: not less than 9 N/mm².

(e) The temperature of the cement at the time of use in the mixing plant must not be higher than 60°C.

If cementing materials (like fly ash or slag) are used, the suitability to meet the special requirements of the final concrete lining will have to be tested and approved by the Engineer.

2.3 Water

The water shall be clean and free of harmful matter in such quantities, as would affect the properties of concrete in the plastic or hardened state.

The water shall satisfy the requirements of potable water.

2.4 Admixtures

Admixtures added to the concrete, must not affect the concrete’s hardening, strength and durability or cause corrosion of the reinforcement.

Chlorides or materials containing chlorides which promote steel corrosion may not be added to reinforced concrete or concrete which comes into contact with reinforced concrete. The prerequisite for the use of admixtures is a qualification test to be performed by the Contractor. The test results must be submitted to the Engineer.

2.5 Structural Concrete Composition

The concrete mix design shall meet the C.S.A 23. 1-00 requirements of a freezing and thawing restricted concrete. The concrete mix used for the intake structure shall furthermore fulfill the requirements of a sulphate-resistant concrete. And in addition, the following requirements shall be met:

- aggregates size 0 mm to 32 mm
- recommended cement volume 270 kg / m³ (maximum)
- recommended cementing material (slag) volume 50 kg / m³ (minimum)
- recommended “blended cement” volume 320 kg / m³
- water / cement ratio ≤ 0.45
- water reducer and / or plasticizers are recommended
- required characteristic strength 35 MPa after 28 days (= long-term strength)
the concrete will have to meet the water infiltration test requirements according to DIN EN 12390 for watertight structures. That means the water infiltration depth, tested with the mentioned method, shall not exceed 30 mm.

2.6 Lean Concrete Composition
The lean concrete composition shall meet the requirements of a grade N concrete, C.S.A. 23.1-00. Its characteristic strength shall be 10 MPa.

2.7 Reinforcement
The reinforcement steel used shall be ribbed steel, grade 500 R or 500 W according to C.S.A. Standard 23.1-00.

In order to improve the composite action and to limit the crack formation, small-diameter reinforcement bars with a small spacing shall be used.

2.8 Contact Grouting Material
The contact grouting material shall be a cement-water suspension with sufficient fluid characteristics to fill the porous cavities and annular space between the final concrete lining and the waterproofing membrane.

If other material is used, they will have to be consistent with the concrete. The consistency has to be demonstrated by test or approved documents and the use of alternative materials has to be approved by the Engineer.

2.9 Compressible Material Layer
The layer shall be stiff enough to cover the stress and strain caused by concrete placement without deformation. At the same time, the layer shall be smooth and flexible enough to transform the long-term underground pressure into deformation so that the structure will not be strained by this kind of loading throughout the facility’s design life time.

For that task, polystyrol material with an original thickness of 10 cm will be used. The layer will be installed at the excavated wall surface of the pit before concreting.

3. Equipment
The works may be performed using any type of equipment approved by the Engineer.

The entire equipment must have a valid quality control certificate and is to be inspected within regular inspection periods.

The design and construction of the formwork moulds is to be evaluated by approved documents (calculations and drawings) and the moulds are to be checked by a Professional Engineer. The results are to be certificated by the Engineer.
4. Transport

All components shall be transported by suitable means of transport and in accordance with industrial safety and road traffic regulations to avoid any damage.

The concrete must not separate while being transported to the construction site and it shall be of the required workability at the location and time of placing.

5. Workmanship

5.1 General

Before starting the concreting works, the Contractor shall develop a concrete works program, which shall contain information on the

- type of concrete production, on site, ready mix
- distance of external plants to the site
- capacity of the mixing plants, additional plants for substitution (incl. distance to the site)
- testing procedure, suitability tests, quality control tests
- thermal development of the concrete during hardening
- schedule of concreting, simultaneous concreting on different sites
- concrete works procedure - use and preparation of formwork, cast-in-place procedure (progress, vibrating, quality supervision)
- formwork replacement (concrete requirements)
- curing

The concrete works programme has to be submitted to the Engineer for approval.

5.2 Formwork

The formwork must be thoroughly cleaned before use. Before concreting, appropriate shutter oil is to be applied to ensure that no concrete will stick to the formwork.

Any formwork support material subject to rust or corrosion is to be removed upon striking of the formwork. Any reinforcement or support material, remaining in the concrete is to be rust and corrosion-proof.

Particular care must be taken in the construction of formwork for the end face of the concrete bays to ensure that the shuttering is especially tight. Without exception, shuttering for end faces must be of smooth-planed boards with parallel, tongue-and-groove jointing; the forms must have a minimum thickness of 20 mm and must be of uniform width. Joints are to be so tight as to be unrecognisable, and the finished wall surface is to be perfectly smooth and even.
The formwork has to be erected and stabilized in such a way, that all stresses and strains caused by the concrete works can be covered. After erection and stabilization, the formwork will be checked and evaluated for its “correct” installation.

The construction elements may only be stripped and the support may only be removed when the concrete has sufficiently hardened. The concrete has sufficiently hardened when the element is strong enough to support all loads, to which it is subjected when stripped, with the prescribed safety.

5.3 Reinforcement

The reinforcement shall - in an approved manner - be stored above ground and shall be protected against aggressive elements. It shall be cut and bent in accordance with the corresponding standards. The tying wire shall be made of soft annealed mild steel with such diameter that all connections required shall be carried out with sufficient stiffness.

The reinforcement arrangement has to be designed, installed and connected in such a way that it is stiff enough to stand without additional support and to minimize deformations and displacements while concreting.

The concrete cover shall be sufficient in accordance with the structural requirements and in compliance with the design. A sufficient concrete cover shall be ensured by concrete spacers, fixed to the reinforcement in sufficient number.

5.4 Concrete Works

5.4.1 CONCRETE PRODUCTION, SITE MIXING PLANT

The aggregates have to be stored on site in separate boxes for gravel, coarse sand and fine aggregates. They have to be protected against dryness, wetness and freezing. For the production of all types of concrete, the individual aggregate components are to be measured by weight using automatic dosing equipment.

The cement and the additives shall be stored in such a way that they will be protected against seasonal influences and that they will keep their original state of quality at the time of delivery. For the concrete production, the components are to be measured by weight, using automatic dosing equipment.

The concrete mixing plant is to be laid out for a separated and automatic batching of 3 different additives. To permit monitoring of the levels of additives added to the concrete mixture, a transparent gauge glass is to be foreseen.

The concrete components (cement, aggregates, water and additives) must be measured with an accuracy of 3%. The weight batching machines shall be carefully maintained and cleaned and provided with simple and convenient means of checking the weighing mechanisms plus they shall be checked when required by the Engineer.

The composition of each type of concrete to be mixed is to be posted at the mixing plant in a clearly legible form and must include the requirements of the given standards. The materials must be mixed in concrete mixers which are suitable for the pertinent concrete composition. The
concrete mixer must be equipped with an electrical current indicator to facilitate regulation of the concrete's consistency. If the specific water content of the aggregates varies, the amount of wet material used plus the amount of mixing water must always be selected in such a way, that the total amount of water remains constant.

The dimensions of the mixing plant have to be sufficient to deliver enough concrete to all relevant sites at any time of the concreting process. All concrete components and the concrete production have to be protected against extreme weather conditions (heat, rain). Mixing plants for sites located in cold weather areas, which may experience frost periods, are to be equipped with mixing water and aggregate heating systems.

A site laboratory, fully equipped to carry out all concrete and concrete component tests required, is to be set up and operated by experienced personnel. An expert in concrete technology and concrete production shall be in charge of this laboratory.

Test mixes are to be made for each type of concrete. The results are to be submitted to the Engineer. The mixes shall be approved by the Engineer and a trial mix shall be prepared under full-scale conditions, including workability tests and cube testing.

5.4.2 READY-MIXED CONCRETE

The entire ready-mixed concrete shall meet the requirements described in this Specification. In addition to this, the Contractor shall submit the name and address of the ready-mix Contractor to the Engineer for approval, stating all the operation and plant details.

The details of the ready-mix Contractor shall include information on the plant, the equipment, the storage depots, as well as the transportation and quality systems. The Engineer shall have access to the ready-mix site for inspection at any time. The Engineer may reject the proposed ready-mix Contractor and may cancel an approval at any time, if the quality of the concrete or the documentation of the control is not satisfactory in the opinion of the Engineer.

The concrete shall in all respects comply with DIN standards, except where amended in this Specification.

All testing of the mixed concrete shall be executed on site.

The Contractor shall ensure that the supplier keeps records of all the required tests and the quality control for mixing and transportation.

The concrete shall be delivered to the site in truck mixers or agitators which are continuously in operation. Each batch delivered must be accompanied by a certificate containing the following information:

- Name of supplier
- Type and grade of concrete
- Mix code number
- Time and date of mixing
- Temperature of mixing
- Additives
- Cement type
- Cement content
- Water cement ratio or quantity of added water
• Time of arrival of truck on site
• Time of end of discharge
• Registration number of truck
• Delivery certificate number

The certificates shall be available to the Engineer for quality supervision.

Any addition of water and admixtures to the concrete after the concrete has been discharged form the mixing plant shall not be accepted.

5.4.3 CONCRETING PROCEDURE

The workability of the concrete shall remain satisfactory until placing and compaction is finished. This shall at a minimum be for 3 hours at 25°C upon arrival on site; this shall also be true for hot weather periods.

During cold weather and frost periods the concrete shall be placed at a specified minimum temperature because of the lower hardening rate and the danger of permanent impairment of defined concrete properties. With ambient temperatures of +5°C to −3°C, the concrete temperature upon placing must not fall below +5°C. With ambient temperatures below −3°C, the concrete temperature must not fall below +10°C.

During hardening, the concrete temperature may not exceed 50°C.

Before the concrete is placed, all formwork elements and surfaces to come into contact with the concrete shall be cleaned from dust, mud and other impurities. The concrete shall not be placed in standing water unless this has been specified or approved.

During placing, suitable means shall be provided to prevent premature hardening of the concrete put in contact with hot surfaces.

When placing concrete in layers, if no construction joints are foreseen, the placing may only be interrupted for a period of time during which the concrete does not set, so that a good and even connection is possible between the two layers of concrete. The concrete shall be placed in level layers of such depth that each layer will be readily and properly mixed with the previous layer below by the use of internal vibrators. The difference in height of the layer’s level on the right hand sidewall and the left hand sidewall of the final lining may not exceed 1 m.

Concreting shall begin in the bottom parts of the sidewalls and shall finish in the crown. Normally the concrete shall be pressed into the formwork. If the formwork is filled by gravity flow, the concrete’s height of fall shall not exceed 1 m.

The type and number of vibrators shall be approved by the Engineer and shall consider the mass and quality of concrete to be compacted and the type of formwork.

The formwork shall be released, when the final concrete lining meets its release strength, measured in the crown by suitable means of measurement.

5.4.4 CURING

The curing of the final lining surface will start immediately after the formwork is released.

When water curing is applied, chill shocks are to be avoided (as could occur when cool water comes into contact with warm concrete surfaces) due to the resulting danger of peeling or
6. **Quality Control**

All components must have a valid quality certificate and a valid permission for the intended use. During the entire period of construction, the Contractor will have to verify the material properties and qualities as defined by the Specifications and Standards. In addition to the tests and investigations contained in the Specifications and Standards, all other tests deemed necessary by the Engineer are to be performed. Records are to be kept of all test results and submitted to the Engineer. The Contractor shall grant the Engineer full access to and use of the laboratory and shall produce on demand the records of all tests carried out.

6.1 **Suitability Tests**

6.1.1 **CONCRETE COMPONENTS**

No aggregates shall be delivered to the site without satisfactory initial sampling and testing. The sample of fine aggregate shall be 25 kg in weight and that of the coarse aggregate shall be 50 kg in weight.

The Contractor's attention is drawn to the need to maintain a consistent aggregate quality and he will be expected to undertake adequate testing to ensure that the quality does not vary significantly (reference is made to Subchapter 6.2, Quality Control Tests).

All components have to be certificated for their origin and quality. The suitability of the components used has to be approved by the Contractor's concrete expert and by the Engineer.

6.1.2 **CONCRETE**

In order to verify the suitability of the concrete compositions for the respective tasks, tests at the site or at the mixing plant have to be carried out for both designed concrete compositions (winter and summer composition). The following items have to be tested using three samples per item under the mentioned conditions:

- **Bulk density**
- **Air void content** (= 3 % to 6 %, maximum)
- **Consistency immediately after mixing and one hour later** (= class F3; DIN 1045-2)
• Release strength after design time for formwork removal
• Characteristic strength after 28 days (= 35 MPa)

6.2 Quality Control Tests

6.2.1 AGGREGATES
The following tests have to be carried out with a frequency of “each delivery”
• grading analyses
• wet analyses
• moisture content, for sand
• organic impurities
• visual inspection of aggregate type, granulometric composition, aggregate condition, particle shape, detrimental components (e.g. coal, humic substances, brittle grains, etc.)
The moisture content of the sand has to be checked in addition once a week.
Chloride and sulphate tests have to be carried out once every 4 months and in case of suspected change.
The tests are to be carried out in accordance with DIN EN 12620.

6.2.2 CEMENT AND CEMENTING MATERIALS
The following tests have to be carried out every 4 months:
• compressive strength
• specific surface
• chemical analysis.
Certificates issued by the supplier shall be tested per storage vessel.
The tests are to be conducted in accordance with the German DIN EN 196 Standard and the requirements of Subchapter 2, Materials.

6.2.3 ADMIXTURES
The certificates issued by the supplier have to be checked at each delivery to the site.

6.2.4 CONCRETE
Fresh concrete has to be tested according to the criteria listed below:

<table>
<thead>
<tr>
<th>testing item</th>
<th>testing frequency</th>
<th>testing procedure</th>
<th>testing moment</th>
</tr>
</thead>
<tbody>
<tr>
<td>consistency</td>
<td>once for every batch on site</td>

</tr>
</tbody>
</table>

The testing procedure and interpretation of the results is described in the above mentioned references. The limit values of the individual tests are specified in Subchapter 2, Materials and Subchapter 6.1, Suitability Tests.

6.2.5 CONCRETE WORKS

The minimum dimensions of the structures shall be the designed dimensions. Smaller dimensions are to be avoided.

If faced with smaller dimensions, the following measures will have to be taken:

<table>
<thead>
<tr>
<th>origin</th>
<th>Extension</th>
<th>consequence</th>
<th>Check</th>
<th>measures</th>
</tr>
</thead>
<tbody>
<tr>
<td>local “breakdown” of formwork</td>

## Technical Specification

### Concrete Works Intake, Outlet Structures

<table>
<thead>
<tr>
<th>origin</th>
<th>Extension</th>
<th>consequence</th>
<th>Check</th>
<th>measures</th>
</tr>
</thead>
<tbody>
<tr>
<td>wrong alignment of formwork</td>
<td>whole concrete section</td>
<td>increase / decrease of structural concrete thickness</td>
<td>sufficient thickness of concrete structure</td>
<td>if maximum flow cannot be achieved, breakdown and reconstruction of concrete section in any other case, smoothening of the surface as described below.</td>
</tr>
</tbody>
</table>

The minimum thickness of the concrete structures shall be the design thickness. Any reduction in thickness shall be avoided. Any increase in thickness shall be limited to the design thickness ± 10 cm. The space available for the placing of the final concrete lining has to be proven by survey of the shotcrete lining surface.

Should the required limits not be met (thinner lining), the area in question should be re-excavated and re-supported. Should the limits be exceeded, the difference between the allowable and the measured thickness shall be compensated by additional shotcrete.

The survey results of the shotcrete surface, as well as the measures to be taken when the limits are exceeded are – in any case – subject to the Engineer's approval.

The surface of the concrete structure shall be smooth and flat. Wedges and bulges are to be avoided, or to be smoothened by grinding. Unevenness shall not exceed 4 degrees (angle of gradient) in all directions.

### 7. Measurements

The quantity survey unit of the concrete shall be $m^3$, the quantity survey unit of the reinforcement shall be ton.

### 8. Acceptance

#### 8.1 Conformity of Work with Design and Technical Specification

The works shall be carried out in accordance with the design, the Technical Specification(s) and the written instructions of the Engineer.
8.2 Acceptance of Works To Be Removed or Covered

8.2.1 DOCUMENTS AND DATA
The acceptance of works which are to be removed or covered shall be based upon:
- a written statement by the Engineer entered into the Site Book that the works have been executed in accordance with the design and the Technical Specification(s),
- other written statements by the Engineer commenting on the execution of the works.

8.2.2 SCOPE OF WORKS
The scope of works to be removed or covered shall be determined by written statements of the Engineer and by other documents confirmed by the Engineer.

1. Introduction

1.1 Subject of Technical Specification

This Technical Specification (TS) shall define the requirements for the execution and commissioning of the waterproofing system in the Diversion Tunnel of the Niagara Tunnel Facility Project.

1.2 Range of Technical Specification Application

This TS is a bid and contract document used for the execution and commissioning of the works referred to in Item 1.1.

The provisions contained in this Specification refer to the working methods to be adopted for the:

a) delivery of all the components and the entire equipment required to the site
b) installation of components required
c) quality control for material and workmanship.

The Scope of Work is defined for the installation of the final lining for the Diversion Tunnel.

1.3 Basic Requirements
1.3.1 GENERAL

A dual layer waterproofing system shall be installed in tunnel sections, where the swelling potential of the rock mass may affect the stability of the tunnel. In all other tunnel sections, a single layer waterproofing system is envisaged (Fig. 1 and Fig. 2).

Fig. 1: Dual layer waterproofing system
1.3.2 SHOTCRETE SURFACE

The basis for the waterproofing system must be constructed in such a way that - taking the material properties into account without any overstress and/or damage being caused - the protective sheet and the loosely installed plastic waterproofing membrane may fit to the shotcrete base as snugly as possibly. In particular:

- all wedges and edges shall be smoothed. The ratio between diameter and depth of local "inaccuracies" shall not be smaller than 10 : 1. The minimum radius shall exceed 20 cm.

- all protruding iron parts shall be removed

- all iron parts, which can not be removed (e. g. heads of rock dowels) shall be covered with shotcrete with a minimum thickness of 3 cm.

- all inflowing water shall be collected and drained off.
1.3.3 REGULATING SHOTCRETE

To meet the shotcrete surface requirements, a thin shotcrete layer, is to be installed where required – independent of the excavation and support procedure. The mechanical properties and the thickness of the so-called regulating shotcrete are to be adapted to the fastening elements (discs) used for the waterproofing membrane and the protective sheet.

1.3.4 GEOTEXTILE FLEECE

To prevent the waterproofing membrane from being damaged when it is pressed against the shotcrete surface, a protective sheet must be provided between the waterproofing membrane and the shotcrete surface.

This sheet should be a geotextile, patched with a thin membrane on one side.

1.3.5 WATERPROOFING MEMBRANE

The waterproofing membrane shall consist of Polyvinylchloride (PVC) or Polyolefin (TPO/FPO).

The materials used must all be permanently resistant to all kinds of external influences and must not be harmed by the usual deformations of structures due to shrinkage, temperature change, or ground movement. The materials used for waterproofing must be compatible with each other and with all other materials they might come into contact with.

1.3.6 JOINT SEALING

In every outside joint of the intake and outlet structure joint tapes shall be placed. The functions of these joint tapes are to seal the joints against liquid inflow and to prevent seepage through the joints.

Depending on the function and location, the following types of joints are distinguished:

- Tunnel Final Lining Joint
Technical Specification

Waterproofing System

Within the final lining joint area the waterproofing membrane will be protected against damage by an additional membrane strip fixed on the membrane by welding. The joint will be sealed against grouting inflow by a kind of geotextile fixed on the front face of the previous concrete bay.

Construction Joints

The construction joints of the intake and outlet structure are sealed with joint tapes (water stops). Injection hoses, installed in the joints to grout the joint surface shall support the waterproofing effect. The injection hoses should be constructed and arranged in such way, that joint grouting will be possible throughout the Diversion Tunnel’s design life time.

Expansion Joints

Expansion joints are sealed with joint tapes, which are suited to keep the joint tight independent of the joint movement. Additional injection hoses shall be installed in the expansion joints.

1.3.7 SLEEVES

To penetrate the waterproofing membrane with hoses for interface grouting and for other devices to be installed outside the waterproofing membrane, special, pre-fabricated sleeves will be provided. These sleeves will be welded on the waterproofing membrane and will surround the hoses in such a way that the location of the membrane penetration is as waterproof as the surrounding waterproofing system.

1.4 General Work Requirements

The Contractor shall be responsible for the quality of material and workmanship and for their conformity with the Design Documentation, other corresponding Specifications, the Method Statements and the Engineer’s instructions.

The Contractor shall provide his personnel with the equipment necessary in accordance with the Specification and shall grant them access to the works to enable them to carry out their work in a safe and proper way.
Before commencing the waterproofing works, the Contractor shall propose a concept for these works. The concept shall comprise the equipment envisaged, the scope of work and the work stages.

2. Materials

2.1 Geotextile Fleece

The protective sheet consists of a geotextile, patched with a thin membrane on one side facing the waterproofing membrane.

The geotextile satisfy have the following minimum requirements:

- Material
  - Polypropylene (PP) or Polyethylene (PE–HD)

- Product identification
  - Manufacturer, thickness, type, production date

- Product appearance
  - Mechanically woven fleece

- Area weight
  - $\geq 600 \text{ g/m}^2, -/+ 5\%$

  Test Method: EN 965

- Melting flow (for PE–HD only)
  - Test Method: DIN ISO 1133
  - Tolerable deviation: $\leq 10\%$

- Thickness under a pressure of 2 kPa
  - Test Method: EN 964–1
  - $\leq 10\text{ mm}$

- Thickness under a pressure of 20 kPa
  - Test Method: : EN 964–1
  - $\geq 4\text{ mm}$

- Tensile breaking force
  - Elongation at break (tension)
  - $\geq 25\text{ kN/m}$
  - $\geq 50\%$
Technical Specification
Waterproofing System

Test Method: EN ISO 12 219

- Perforation force
  Test Method: EN ISO 12 236
  $\geq 8 \text{ kN and} \leq 20 \text{ kN}$

- Elongation at perforation
  Test Method: EN ISO 12 236
  $\geq 50 \%$

- Storage in salt water (10% NaCl)
  at 23° C for 28 days
  Test Method: DIN 16 726, 5.18
  Reduction in tensile strength $\leq 25 \%$
  Reduction in tensile elongation $\leq 25 \%$

- Storage in sulfuric acid (5%)
  at 23° C for 28 days
  Test Method: DIN 16 726, 5.18
  Reduction in tensile strength $\leq 25 \%$
  Reduction in tensile elongation $\leq 25 \%$

- Storage in caulk water (saturated with Ca(OH)$_2$
  at 23° C for 28 days
  Test Method: DIN 16 726, 5.18
  Reduction in tensile strength $\leq 25 \%$
  Reduction in tensile elongation $\leq 25 \%$

- Fire resistance
  Non flammable

The patched backing membrane shall satisfy the following minimum requirements:

- Material
- Product identification
- Product appearance
- Thickness
- Materials
- Tensile breaking force
- Elongation at break

Polyolefin (FPO or TPO)
Manufacturer, thickness, type, production date
No blisters, cracks, nests or holes
Minimum 0.3 mm
Polyolefin (FPO or TPO)
$\geq 25 \text{ kN/m}$
$\geq 300 \%$
2.2 Waterproofing Membrane

The waterproofing membrane shall satisfy the following minimum requirements:

- Material
- Product identification
- Product appearance
- Straight deviation and evenness
  Test Method: DIN 16 726, 5.2
- Single membrane thickness
- Dual membrane thickness
- Thickness signaling layer
- Density
  Test Method: DIN 53 479
- Melting flow
  Test Method: DIN ISO 1133
- Breaking strength (tear)
  Elongation at break (tear)
  Test Method: DIN 16 726, 5.6.1
- Module of Elasticity between 1 and 2 % elongation

Polyolefines (FPO or TPO)
Manufacturer, thickness, type, production date
No blisters, cracks, or nests, full areal bond between signal layer and membrane
Deviation from straight \( \leq 50 \text{ mm} \)
Evenness \( \leq 10 \text{ mm} \)
3.0 mm (mean), \(-/+ 5 \%\)
2.0 mm + 1.5 mm (mean), \(-/+ 5 \%\)
\( \leq 0.2 \text{ mm} \)
Tolerable deviation:
+ 0.03, \(-0.003 \text{ g/cm}^3\)
Tolerable deviation:
\( \leq 10 \% \)
> 15 N/mm²
> 500 %
< 100 N/mm²
Technical Specification
Waterproofing System

Test Method: DIN 16 726, 5.6.2

- Multiaxial tension (bulge test)
  Test Method: DIN 53 861

- Shear test for welded seams
  Test Method: DVS 2226-2

- Peel test for welded seams
  Test Method: DVS 2226-3

- Resistance against water pressure
  Test Method: DIN 16 726, 5.11

- Perforation
  Test Method: DIN 16 726, 5.12

- Storage at 100°C for 1 hour
  Test Method: DIN 16 726, 5.13.1

- Storage in water at 80°C for 70 days
  Test Method: DIN 16 726, 5.13.3

- Storage in water at 50°C for 8 months
  Test Method: SIA-V 280, test 13

- Storage in salt water (10% NaCl) at 23°C for 28 days
  Test Method: DIN 16 726, 5.18

- Storage in sulfuric acid (5%) at 23°C for 28 days
  Test Method: DIN 16 726, 5.18

- Storage in caulk water (saturated with)
  Reduction in tear strength ≤ 20%

Tolerable deviation:
> 50% of 1,0 m dia. sample

Break outside seam, shear strength factor ≥ 0.9

Peel resistance ≥ 0.8 * thickness * tension stress [N/mm²]

No leakage at pressure of 30 bar over 72 hours

No perforation for test tool of 500 g weight falling from 750 mm

Change of dimensions ≤ +/- 2%
No blister formation

Reduction in tensile strength ≤ 20%

Reduction in tear strength ≤ 20%
Reduction in tear elongation ≤ 20%

Reduction in tear strength ≤ 20%
Reduction in tear elongation ≤ 20%
Technical Specification
Waterproofing System

Ca(OH)₂
at 23°C for 28 days

Test Method: DIN 16 726, 5.18

- Fire resistance

Reduction in tear elongation ≤ 20%

Non flammable

The inner layer of dual membranes shall have dimples with 2 – 3 mm diameter, 0.5 mm high spacing 20 mm approx. to provide a space between the two membranes for vacuum testing.

2.3 Joint Tapes

2.3.1 JOINT TAPES FOR CONSTRUCTION JOINTS, EXPANSION JOINTS

The joint tapes (water stops) for the waterproofing of construction and expansion joints shall be manufactured from non-reclaimed, durable, weldable plasticized PVC of a oil- and bitumen-resistant material quality, using softening agents with a polymer molecular structure.

The minimum material requirements shall be as follows:

- ultimate tensile strength
  at + 23°C (acc. to EN ISO 527) > 10 N/mm²
  at + 23°C (acc. to EN ISO 527) > 350 %
  at - 20°C (acc. to EN ISO 527) > 200 %

- elongation at break

- minimum thickness, construction joints: 3.5 mm
- minimum thickness, expansion joints: 4 mm

3. Equipment

The works may be performed using any type of equipment approved by the Engineer.
4. Transport

All components shall be transported by suitable means of transport and in accordance with industrial safety and road traffic regulations to avoid any damage.

5. Workmanship

5.1 Tunnel

Before starting the waterproofing works in the tunnel, the shotcrete surface of the initial lining shall be reviewed for its suitability for the works anticipated. The requirements, described in chapter 1 indicate the criteria of suitability.

5.1.1 REGULATING SHOTCRETE

At locations at which the required surface condition has not been met, regulating shotcrete must be applied. The following minimum requirements shall be met:

1. Adequacy of mechanical properties
2. Minimum thickness 30 mm
3. The ratio of diameter to the height of local "inaccuracies" due to excavation must be at least 10:1
4. Filletings with a minimum radius of 0.20 m
5. Care is to be taken that all rebound is removed, especially in the invert.
5.1.2 GEOTEXTILE FLEECE

Before installing the geotextile fleece as a protective sheet, the regulating shotcrete must be checked by the Contractor of the waterproofing system works and acceptance must be stated in written form.

The protective sheet is delivered and installed onto the surface of the regulating shotcrete in strips fixed by fastening elements (discs). Depending on the weight of the protective sheet, 3 discs per m² should be positioned at the tunnel roof, while 2 discs per m² should be sufficient at the sidewalls and the invert.

The overlapping of the strips should not be smaller than 100 mm.

5.1.3 WATERPROOFING MEMBRANE

The waterproofing membrane is delivered in rolled strips. The strips are welded onto the above mentioned discs (Fig. 3). Dual membrane elements are delivered with prefabricated seams. Only the minimum amount of seems required for installation shall be produced on site (Fig. 4).

The connection between the waterproofing membrane and the fastening elements must be inferior in strength to the connection between the individual strips of waterproofing membrane. If subjected to extremely high stresses, the waterproofing membrane should break loose from the fastening elements, preventing damage being done to the membrane itself.

The strips are connected by welding with flat-face fillet welds; solid seams are not permitted in the standard case. Controllable double seams (Fig. 5) are provided at each joint. The control space of the double seam must be at least 10 mm wide, but must not exceed 20 mm. T-joints as well as repair works may be carried out as solid seams of at least 30 mm. Cross-joints shall be avoided. Welding has to be carried out in accordance with the temperature range specific for the material used. Seams must not be welded at temperatures below +5°C, unless special measures are taken, which are approved by the Engineer.
Fig. 3: Installation of the single layer waterproofing system

In the tunnel invert, where the precast invert concrete segment is laid ahead of the final lining vault, the installed waterproofing system segment (geotextile and waterproofing membrane) has to be covered with suitable measures, to prevent damage (reference is made to the corresponding drawing no. PD-01–1020).

Fig. 4: Connection of dual layer waterproofing membrane
5.1.4 SLEEVES

Waterproofing membrane strips with welded sleeves shall be prefabricated and delivered to the site. The hoses shall carefully be inserted into the sleeves, following the manufacturer’s order.

The hoses and sleeves shall be fixed and protected in such a way that no moving, cracking or other damage will occur during concreting.

Pre-fabricated sleeves shall be provided to penetrate the waterproofing membrane with grouting hoses and for other devices to be installed through the waterproofing membrane. These sleeves shall be welded on the waterproofing membrane and will surround grouting hoses and such devices in such a way, that the location of the membrane penetration is waterproof (Fig. 6 and 7).
5.2 Intake, Outlet Structure

Considering the width of the structure, the required joint tapes shall be located within the joint as close as possible to the outside face of the concrete structure. They shall be installed and fixed in such way that no moving, bending or any other kind of damage will occur during concreting. The injection hoses shall be installed in such way that the joints can be sealed against water from the inside and the outside over the entire length. The grouting procedure shall be possible to be repeated at any time throughout the lifetime of the structures.

Required field connections shall be welded by experienced personnel according to the manufacturer’s or the Employer’s instructions.

At the interfaces to the tunnel structure, the intake /outlet structures are sealed with joint tapes, which are welded on the waterproofing membrane on the Diversion Tunnel side and inserted in the structural concrete of the intake and outlet structure.
6. Quality Control

6.1 Suitability Tests

Suitability tests as specified in section 1 must be carried out by the manufacturer for all components of the waterproofing system. The test procedure and the material performance have to be certified by an officially approved checking organisation.

6.2 Testing During Production

During production of plastic components of the waterproofing system, tests have to be performed, which cover the following requirements and are documented by the manufacturer at specified intervals and the checking organisation at 6 month intervals.

6.2.1 GEOTEXTILE FLEECE WITH BACKING MEMBRANE

- Material

6.3 Testing on Site

6.3.1 GEOTEXTILE FLEECE

The product sheets containing test results for items specified in 3.2.1 shall be checked on site for each delivery. Only fleece materials, which do meet the specified requirements may be installed in the tunnel.

6.3.2 WATERPROOFING MEMBRANE

The product sheets containing test results for items specified in 3.2.2 shall be checked on site for each delivery. Only membrane materials, which do meet the specified requirements may be installed in the tunnel.

Dual layer membrane systems shall be tested by connection of the test hoses to a vacuum system. Each compartment is to be tested before concreting of the final lining (Fig. 8). Initially – 0.7 bar of vacuum pressure shall be applied until after 10 minutes – 0.5 bar testing pressure is installed. The pressure shall be recorded for 15 minutes. The test is considered as passed, if the pressure drop after 10 minutes does not exceed 20% (= 0.1 bar) of the applied test pressure. Repair before
concreting is carried out with additional layers of membrane welded on to the damaged areas.

Fig. 8: Testing of compartments

Single layer membrane systems shall be visually inspected and the inspection documented, before concrete is placed.

The double seams of the waterproofing membrane produced on site are to be tested with compressed air of 2.0 to 2.5 bar. In the test, the pressure is applied at one end of the test section and measured at the other end. The test is considered as passed, if the pressure drop after 10 minutes does not exceed 20% of the applied test pressure.

T-joints, repair seams and sleeves for penetration through the membrane shall be tested with a vacuum bell jar applying a low pressure of 0.2 bar over 10 minutes.

Tests and QA/QC inspections have to be carried out and documented accordingly.

6.4 Joint Tapes

The Contractor shall furnish the Employer with copies of the manufacturer’s test certificates for the water stops to be supplied.
7. Measurements

The quantity survey unit of the waterproofing system components (geotextile and membrane) shall be m². The quantity survey unit of the joint tapes shall be m.

8. Acceptance

8.1 Conformity of Work with Design and Technical Specification

The works shall be carried out in accordance with the design, the Technical Specification and the written instructions of the Engineer.

8.2 Acceptance of Works To Be Removed or Covered

8.2.1 DOCUMENTS AND DATA

The acceptance of works which are to be removed or covered shall be based upon:

- a written statement by the Engineer entered into the Site Book that the works have been executed in accordance with the design, the documentation and with the Technical Specification(s),
- other written statements by the Engineer commenting on the execution of the works.

8.2.2 SCOPE OF WORKS

The scope of works to be removed or covered shall be determined by written statements of the Engineer and by other documents confirmed by the Engineer.

9. Applicable Regulations

1. Introduction

1.1 Subject of Technical Specification
This Technical Specification (TS) shall define the requirements for the execution and commissioning of drainage measures in the Diversion Tunnel of the Niagara Tunnel Facility Project.

1.2 Range of Technical Specification Application
This TS is a bid and contract document used for the execution and commissioning of the works referred to in Item 1.1.

The provisions contained in this Specification refer to the working methods to be adopted for the:

- delivery of all the components and the entire equipment required to the site
- installation of drainage measures
- quality control for material and workmanship.

The Scope of Work is defined for the excavation and support procedure to be adopted for the Diversion Tunnel.

1.3 Definitions
The basic definitions given in this TS are in conformity with the relevant standards in force.

In general, two types of measures may be distinguished with respect to drainage:

- Drainage of water seeping into the tunnel through the initial lining or the tunnel face
- Treatment of water from the surrounding rock mass to increase rock mass stability and limit rock mass permeability

Subsequently, the respective components shall be described:

1.3.1 DRAINAGE MATS
Drainage mats are geotextiles with a watertight surface on the front side and a permeable medium on the back side. They will be fixed to the shotcrete of the initial lining in case of extensive water inflow through the shotcrete lining.

1.3.2 DRAINAGE PIPES
Drainage pipes are flexible plastic pipes, with a diameter between 1” and 2”. They are used to drain the inflow of water at certain locations of the shotcrete lining. Several pipes can be interconnected with pipe fittings to create one “collection pipe”.

© ILF 2005
.3.3 INVERT DRAINAGE

The water of all these drainage systems is collected in a pit, located in the precast concrete invert segment. This pit offers sufficient space to retain the incoming water and drain it to the collection tank.

.3.4 PUMP SUMPS

In a downhill tunnel excavation, pumps sumps are to be installed approx. every 30 m on both sides of the excavation in the vicinity of the tunnel face to collect and remove the water coming from the excavated and supported tunnel area.

These pump sumps shall have a diameter of not less than 800 mm and a depth of not less than 1 m. The walls should be covered with precast concrete elements or with shotcrete. The bottom shall feature a pumping pit and shall be covered with shotcrete. The pumps shall remove the water by pipes, fixed to the sidewalls, to the portal areas or to nearby collection points.

.3.5 COLLECTION TANK

At the lowest point of the tunnel, a tank with sufficient volume shall be installed to retain the water collected in the tunnel. The tank shall be equipped with two pumps (redundant system) to avoid flooding. The tank can be excavated beneath the invert and supported with a reinforced shotcrete lining or installed as a mobile basin.

During the downhill excavation and while approaching the lowest point of the tunnel, a mobile collection tank shall be attached to the tunnel boring machine behind the gantry, for the water from the tunnel backside and the excavation area to be collected and pumped out.

.3.6 SETTLING TANK

The water collected in the tunnel might on the one hand be mixed with suspended sediments and settleable particles and might on the other hand be polluted with liquids like oil etc. And it might be alkaline in composition due to the cement components contained in the shotcrete.

In view of these facts and in response to the environmental requirements, a settling tank with a light oil separator, and depending on the pH-value - with a neutralization facility shall be installed. The settling tank shall be constructed in such a way that the environmental requirements for the water to be conveyed into any existing watercourse can be fulfilled.

The settling tank can be constructed as an earth basin, supported by reinforced shotcrete or as a precast steel basin. The light oil separator shall be installed at the basin’s intake, the neutralisation facility at the basin’s outlet.

The intended neutralisation process, with sulphuric acid or carbonic acid, shall be submitted to the Engineer for approval. Neutralisation with hydrochloric acid shall be avoided, due to the health risk and the danger to the environment.
1.3.7 WATER TREATMENT OF SURROUNDING ROCK MASS

To reduce the permeability of the surrounding rock mass, the area in the vicinity of the tunnel is sealed by grouting. Details regarding this procedure are presented in the corresponding Specification “Underground Grouting”.

1.4 General Work Requirements

The Contractor shall be responsible for the quality of material and workmanship and for their conformity with the Design Documentation, the General Technical Specification, the detailed Technical Specification and the Engineer’s instructions.

2. Materials

Reference is made to Item 1.4 – Definitions. The material depends on the manufacturer and the construction method.

3. Equipment

The works may be performed using any type of equipment approved by the Engineer.

The entire equipment must have a valid quality control certificate and is to be inspected within regular inspection periods.

The pumps, the necessary pumping pipes, as well as all other components previously mentioned, will have to be sufficient in dimension to safely remove the local water inflow.

At the entrance of the settling tank, a measuring unit shall be installed to quantify the amount of water.

4. Transport

All components shall be transported by suitable means of transport and in accordance with industrial safety and road traffic regulations to avoid any damage.

5. Workmanship

The Contractor shall present an organisation chart and a time schedule to the Engineer for approval, giving due consideration to all conditions accompanying the execution of the works.

All components will have to be installed with such care that the success of the measures is guaranteed at any time.
5. **Quality Control**

All components must have a valid quality certificate and a valid permission for the intended use.

The quality of the measures taken has to be controlled by permanent visual inspection. The quality of the water released into the watercourse has to be monitored at regular intervals in accordance with the relevant environmental requirements.

7. **Measurements**

The quantity survey units of the individual components shall be:

- Drainage mats: $m^2$ of mats installed
- Drainage pipes: $m$ length of pipes installed
- Invert drainage: $m$ of drainage installed and operating satisfactorily
- Pump sumps: piece of pump sump(s) installed
- Settling tank: piece of settling tank(s) installed incl. all additional components
- Installation of equipment: 1 piece
- Timeframe per measure: day of operation

3. **Acceptance**

3.1 **Conformity of Work with Design and Technical Specification**

The Works shall be carried out in accordance with the design, the Technical Specification(s) and the written instructions of the Engineer.

3.2 **Acceptance of Works To Be Removed or Covered**

3.2.1 **DOCUMENTS AND DATA**

The acceptance of works which are to be removed or covered shall be based upon:

- a written statement by the Engineer entered into the Site Book that the works have been executed in accordance with the design and the Technical Specification(s),
- other written statements by the Engineer commenting on the execution of the works.

3.2.2 **SCOPE OF WORKS**

The scope of works to be removed or covered shall be determined by written statements of the Engineer and by other documents confirmed by the Engineer.

1. Introduction

1.1 Subject of Technical Specification

This Technical Specification (TS) shall define the requirements for the execution and commissioning of tunnel excavation and support works in the Diversion Tunnel at the Niagara Tunnel Facility Project.

1.2 Range of Technical Specification Application

This TS is a bid and contract document used for the execution and commissioning of the works referred to in Item 1.1.

The provisions contained in this Specification refer to the working methods to be adopted for the:

a) delivery of all the components and the entire equipment required to the site
b) excavation of required tunnel cavity by drilling and blasting or mechanical excavation
c) mucking and storage of excavated material
d) installation of required support measures
e) quality control for material and workmanship.

The Scope of Work is defined for the Diversion Tunnel at the tunnel connection area to the outlet and the intake structure during the excavation and support period.

1.3 Definitions

The basic definitions given in this TS are in conformity with the relevant standards in force.

1.3.1 EXCAVATION AND SUPPORT TYPES

The excavation and support works have to be carried out, in compliance with the excavation and support type documentation. This documentation states the allowable excavation volume per round, i.e. the span and the cross-section area of
the next excavation step and type, as well as the extent and location of the required support measures.

The excavation and support types have been designed based upon the rock mass description and the rock mass behaviour description.

The application of the different excavation and support types at the works is to be determined on site by experienced personnel and by arrangement with the Engineer, taking into account the local geology, verified by visual inspection and documentation, as well as the deformation of the excavated and supported tunnel area, verified by geotechnical measurements and monitoring.

1.3.2 EXCAVATION AND SUPPORT OF TUNNEL ENTRANCE / EXIT AREA

At the tunnel entrance and exit area, the tunnel cross-section is changing from square shape at the intake / outlet interface to circular shape within a stretch of 20 m. This tunnel stretch will be excavated by drilling and blasting adopting the principles of the New Austrian Tunnelling Method (NATM).

1.3.3 MINED TUNNEL PORTAL

For the mined tunnel portal at the intake / outlet, a special excavation and support technique is intended to be employed, taking the cross-section form and the “starting procedure” into account. For this procedure to be adopted, the entire edge of the excavation cross-section is supported with reinforced shotcrete. To limit the excessive breakout of rock mass, caused by blasting, rock dowels with a minimum length of 6 m shall be installed horizontally on top of the crown of the tunnel.

The excavation, by blasting, shall be done in several steps and for the support of the excavation surface, reinforced shotcrete and rock dowels shall be installed immediately after excavation.

1.3.4 DRILLING AND BLASTING

Tunnel excavations involving drilling and blasting shall only be carried out by experienced, well trained personnel. At an early stage, in advance of the proposed use of explosives, the Contractor shall inform the Engineer, third parties, statutory authorities and services which have an interest in the project or are likely to be affected by the blasting operations, of the general nature of the operation. The
Contractor shall – in due time (at a minimum a fortnight) – subsequently notify the Engineer and all others listed above of the intended use of explosives.

With this notification, the Contractor will submit to the Engineer’s approval a detailed method statement considering all aspects of the intended use.

1.3.5 MECHANICAL EXCAVATION, TUNNEL BORING MACHINE

The circular Diversion Tunnel will be excavated with a tunnel boring machine (TBM). In response to the rock mass conditions, a so-called “gripper machine” will be installed.

The tunnel boring machine shall be designed and constructed in such a way that

- horizontal and vertical alignment requirements are met
- the differing conditions of the surrounding rock mass, e.g. rock strength and rock mass strength, parting plane structure can be governed
- the minimum clearance necessary will be achieved for the proper construction of the works and the overbreak will be limited to a minimum
- provisions will be made to resist rotation of the tunnel boring machine
- all materials used will be fire resistant.
- an effective fire-fighting system will be installed on the machine
- adequate access will be granted to all areas of the TBM where work, including maintenance, may have to be carried out

In the design and manufacturing of the TBM it must be ensured that no contamination of excavated material will take place. Material contaminated during the excavation process shall be handled by the Contractor.

Further detailed specifications are described in Subchapter 3, Equipment and Subchapter 5, Workmanship.

1.3.6 MUCKING

The excavated rock material will be mucked out by a belt conveyor, installed at the sidewall of the tunnel.
1.3.7 MATERIAL DEPOSIT

The excavated material will be deposited as required by the Owner. It will be placed in layers of approximately 0.5 m and compacted according to the storage requirements.

On the designated storage area, a temporary deposit for contaminated materials will be installed. The temporary deposit shall cover a volume of 60,000 m³ at a maximum (complying with a 15 workday excavation progress).

To meet this requirement, the storage area shall cover a base area of approx. 100 m x 200 m. The material shall be stored in such a way that the slopes will be stable under normal weather conditions. The temporary deposit is sealed against the underground with an impermeable base and surrounded by peripheral ditches and drains to capture any runoff. The runoff will be collected in a separate settlement basin and suitably treated prior to discharge into the water treatment plant of the temporary tunnel drainage.

1.3.8 SUPPORT INSTALLATION

Depending on the defined support types (see above) the respective support measures shall be implemented as described in the corresponding drawings. The support elements which comprise

- reinforced shotcrete
- steel H-beams and steel U-profiles
- rock dowels

are listed in the corresponding Specifications. For the installation of the support elements, a differentiation is made between an area within the TBM, right behind the cutter, and an area behind the TBM. The installation of the support elements will interrupt or even govern the TBM advance.

1.4 General Work Requirements

The Contractor shall be responsible for the quality of material and workmanship and for their conformity with the Design Documentation, other corresponding Specifications and Method Statements and the Engineer’s instructions.
The Contractor shall provide his personnel with the equipment necessary in accordance with the Specification and shall grant them access to the works to carry out their work in a safe and proper way.

Before commencing the works, the Contractor shall propose a concept to the Engineer for approval. The concept shall comprise the equipment envisaged, the scope of work and the work stages.

2. Materials

2.1 Explosives

The mandatory requirements of the Owner will be considered. In addition to that the following items are obligatory as well.

Only licensed explosives and detonators shall be used. Explosives and detonators shall be stored in separate vessels, which shall be protected against damage and misuse. The storage volume on site shall not exceed the needs of two days.

The explosives and detonators used shall be safe in handling until the intended time of use. Explosives shall only be handled and used by the Contractor’s duly authorised personnel. The names and qualifications shall be submitted to the Engineer in writing prior to any possible use of explosives.

All statutory requirements for the storage and use of explosives have to be considered. The Contractor shall give notice about the use and storage of explosives to the Engineer and all security services and responsible authorities for approval. This information shall contain

- the volume and type of explosives and detonators stored on site
- the type, construction and location of the different storage vessels
- the authorised personnel with name and qualification
- the shot-firer's name and qualification
- the design of the used blasting system with information about the specific volume of explosives (g explosives / m³ excavation) and the number and firing sequence of the detonators.
2.2 Support Elements

The material and handling of the support elements listed above is described in the corresponding Specifications. Reference is made to the

- "Technical Specification Shotcrete"
- "Technical Specification Reinforcement"
- "Technical Specification Rock Dowels"
- "Technical Specification Steel Ribs"

3. Equipment

The works may be performed using any type of equipment approved by the Engineer.

The entire equipment must have a valid quality control certificate and is to be inspected and maintained within regular inspection and maintenance periods.

3.1 General Construction Plants

For excavation by drilling and blasting, within the tunnel entrance / exit areas the Contractor will use a driller for the boreholes and the rock dowel installation and a shotcrete installation plant depending on the method applied (wet or dry shotcrete).

For general delivery and transportation services within the tunnel, trains will be used. A train station will be installed in the lowest part of the tunnel.

A list of construction plants intended to be used and a concept of transportation will be submitted to the Engineer for approval.

3.2 Tunnel Boring Machine (TBM)

In addition to the general definitions (reference is made to Subchapter 1.3.5, Mechanical Excavation, Tunnel Boring Machine) the TBM shall satisfy the following requirements:

- Installation of steel ribs, shotcrete and rock dowels immediately behind the cutter head.
• Installation of steel ribs, wire mesh, shotcrete and rock dowels from the working platform between the TBM and the gantry, providing ring closure after approximately 40 m.

• Installation of shotcrete and rock dowels from the TBM gantry.

• Arrangement of gripper system in such a way that the support measures to be installed behind the cutter hand will not be obstructed by the position of the grippers.

• Provision of steering and gripper system suitable for hard rock and deformable soft rock.

• Provision of probing facility suitable to drill at least 15 m ahead of the excavation face, without interruption of the TBM advance cycle.

• Provision of access facility in the front of the cutter head for maintenance and other works.

• TBM operation, unimpaired by a damp and wet working environment.

• Maintenance of cutting tools possible at all times from the rear side or the front side of the cutter head.

• cutterhead with minimum peripheral exposure

• cutterhead with Variable Frequency Drive (VFD), fully reversible and allowing increased torque at startup

• hydraulic roof support offering immediate rock support at the rear of the shield "fingers" with full support to protect the workers

• two sets roof drills mounted on a ring gear behind the cutterhead with independent control and bolting while boring, coverage is 360 deg. The rock drills will be designed and equipped to execute cavity grouting and formation grouting from the top of the TBM.

Instantaneous penetration rates for the TBM have been estimated by 2 reputable TBM manufacturers. The estimates are based on proprietary models developed by Robbins and Wirth including studies carried out by the Colorado School of Mines, NTH (Norwegian Institute of Technology) and others.
Based on STRABAG’s empirical data in similar rock formations and in order to allow for the anticipated mixed face conditions, the instantaneous penetration rates obtained from the manufacturers have been reduced by applying a factor of 0.75.

Due to the potential gassy conditions, the TBM will be designed with an electrical system to Class I Div II specifications. In addition, the TBM will be fitted with a methane monitoring system, which consists of a 3 sensor system. The first sensor provides for continuous methane monitoring in the cutterhead, the second sensor is located in the vicinity of the operator and the third senses the ventilation exhaust discharge. Automatic shut down of the main power is accomplished at pre-set levels.

In a methane event the essential services will remain on and will be supplied as a Class I Div I explosion proof system these services include:

- Emergency lighting
- Ventilation
- Power for discharge pumps (pump not included)
- Communications
- Methane monitor

### 3.3 Belt Conveyor

The belt conveyor has to be designed and constructed in such a way that:

- the excavated rock material can be mucked out in the required volume and with the required progress without any interruption of the TBM advance for mucking
- the excavated material will be transported in a safe way and the working personnel will be protected against any kind of incident / accident
- an emergency stop is possible at any time
- the conveyor is protected against misuse

A detailed specification, including an installation plan will be given to the Engineer for approval.
3.4 Tunnel Ventilation

Ventilation ducting shall be non-combustible.

Atmospheric tests shall be carried out continuously to determine the concentrations of the following contaminants and to ensure that the oxygen content of the atmosphere is at least 20%.

- Carbon dioxide
- Carbon monoxide
- Hydrogen sulphide
- Methane
- Sulphur dioxide
- Nitrogen oxides
- Oil vapour
- Silica dust

The exposure of any person to silica dust shall not exceed internationally recognised limits, which are approved by the Engineer.

In case of changes in the work procedures or changes in ground conditions, the reference dust measurements shall be checked with traditional documentation measurements.

The procedures for corrective actions shall be described in the emergency plan.

Recirculation of cleaned air will not be accepted.

3.5 Dust control

3.5.1 Dust prevention in the cutterhead

The dust suppression system consists of nozzles on the cutterhead to suppress dust produced by the boring operation. The water or foam passes through a rotary swivel mounted on the back side of the cutterhead.
The flow can be adjusted according to prevailing ground conditions. Water or foam can also be sprayed in hoppers to wet the excavated material.

3.5.2 Dust control in the tunnel.

Dust control is provided by the design of air flow and the use of dust shields, which are circulation in the lace area is provided by suction. Through careful attention to air flows, the dust is controlled and confined to dust production areas and then carried by piping to the air scrubber system. The air scrubber fans are mounted on and are part of the trailing backup system.

4. Transport

All components shall be transported by suitable means of transport and in accordance with industrial safety and road traffic regulations to avoid any damage.

5. Workmanship

5.1 Drilling and Blasting

Boreholes intended to be charged with explosives for blasting shall be drilled in strict accordance with the agreed pattern in spacing, direction and depth.

No borehole shall be charged until completion of all drilling operations at the face.

Blasting operations shall be carried out only under the direction of an experienced operator and explosives shall only be handled by shot-firers. The Contractor will appoint one competent person to be responsible for the security of explosives.

Blasting shall be carried out carefully so as to avoid the loosening or shattering of rock beyond the required line of excavation. All loose or shattered rock shall be removed by scaling down or other means before personnel will be permitted to restart operation after blasting.

If required, the neighbourhood of the blasting location has to be protected against "flying" rock pieces.
To extract the explosive gases, a minimum fresh air ventilation of 15 minutes is obligatory before the personnel is permitted to resume operations on site.

Notices of blasting operations shall be posted on site. Before each firing, the responsible shot-firer shall give audible warning, clear the area and take measures to prevent personnel from entering the danger area.

No person shall be allowed to approach the face and no face operation shall commence until the authorised person in charge of the operation has given permission.

The results of blasting shall be monitored closely and where appropriate changes of the blasting operation shall be proposed for agreement of the Engineer.

5.2 TBM Operation

5.2.1 INFORMATION TO BE PROVIDED

As part of this Proposal an outline specification of the TBM intended for use is provided.

In addition to full mechanical and electrical details, an assessment of maximum, average, and intended progress rates is to be provided, supported by records from existing machines of the same type under similar ground conditions. The name of the proposed TBM manufacturer shall be stated with information on his experience, production capacity, etc.

5.2.2 INSPECTION OF FACILITIES

The Contractor is to allow the Engineer full inspection of the machine facilities during fabrication or adaptation, testing, installation and commissioning.

5.2.3 MACHINE MAINTENANCE

The Contractor shall provide the Engineer with a proposed machine maintenance schedule, including a list of maintained spare parts and available periods for assessment and acceptance. Details outlining the cooperation and the split responsibilities between the TBM manufacturer and the Contractor shall be given.
Use of the machine shall not commence until the maintenance schedule is agreed.

5.2.4 PERSONNEL TRAINING

Evidence shall be produced to the Engineer that

- the senior personnel has had previous experience regarding the operation of similar TBMs under similar ground conditions
- the operating personnel has had previous TBM experience or has undergone training in day to day machine use, steering and operation
- the entire personnel has been trained in emergency procedures

5.2.5 WORKING ENVIRONMENT

The TBM shall be designed in such a way that working conditions during operation and maintenance fulfil the health and safety requirements. Care shall be taken regarding working postures, accessibility, quality of air and noise level.

5.3 Installation of Support Elements

In advance of every excavation and support step, the intended excavation and support type for the execution has to be determined in writing by the Contractor’s Representative and agreed by the Engineer. The record’s shall contain but shall not be limited to such facts as:

- Excavation area (from chainage to chainage)
- Determined excavation and support type (according to described types)
- Length of unsupported excavation area (round length)
- Specifications of the individual support elements, like thickness of shotcrete lining, kind of reinforcement, kind and length of steel ribs, number, arrangement, type and length of rock dowels
- Place of support installation, right behind the cutter head, between TBM and gantry, behind the gantry
- Additional measures like dewatering measures, grouting measures, etc.
- Measurement installation, type, location, arrangement
The works shall be carried out in compliance with this record. The decision regarding the excavation and support type to be applied will have to be evaluated at every excavation round and will have to be adapted to the local geological and geomechanical conditions of the surrounding rock mass.

The support elements will have to be installed in such a way that they are effective with respect to their required use.

Sufficient quantities of every individual support element will have to be stored on site, to react to unforeseen events, caused by unforeseen rock mass behaviour.

In addition to the designed support elements, liner plates and timber struts in sufficient number and dimension will have to be stored on site.

For reasons of personnel safety, the work site has to be kept safe at any time and as long as necessary for the personnel to be evacuated.

6. Quality Control

All components must have a valid quality certificate and a valid permission for the intended use.

6.1 Quality Test

All materials and components have to be tested with respect to their specific use. Records of the testing shall be produced and submitted to the Engineer for approval. If necessary, adaptations of materials and components have to be made.

Quality tests of all delivered materials have to be carried out regularly. The equipment has to be inspected and maintained periodically to prevent failure during operation.

6.2 Control of Workmanship

The works have to be guided and supervised by experienced personnel. The excavation and support works shall be recorded for every shift. The records shall contain, but shall not be limited to the following information:

- Number of workmen within the team
7. Measurements
The quantity survey unit for excavation shall be \( m^3 \) of excavated material.

8. Acceptance

8.1 Conformity of Work with Design and Technical Specification
The works shall be carried out in accordance with the design, the Technical Specification and the written instructions of the Engineer.

8.2 Acceptance of Works To Be Removed or Covered

8.2.1 DOCUMENTS AND DATA
The acceptance of works which are to be removed or covered shall be based upon:
- a written statement by the Engineer entered into the site Book that the works have been executed in accordance with the design and the Technical Specification(s),
- other written statements by the Engineer commenting on the execution of the works.

8.2.2 SCOPE OF WORKS

The scope of works to be removed or covered shall be determined by written statements of the Engineer and by other documents confirmed by the Engineer.

1. Introduction

1.1 Subject of Technical Specification

This Technical Specification (TS) shall define the requirements for the execution and commissioning of excavation and support works for the Dewatering System in the Diversion Tunnel of the Niagara Tunnel Facility Project.

1.2 Range of Technical Specification Application

This TS is a bid and contract document used in the execution and commissioning of the works referred to in Item 1.1.

The provisions contained in this Specification refer to the working methods to be adopted for the:

a) delivery of all components and the entire equipment required to the site
b) drilling of required boreholes
c) mucking and disposal of excavated material
d) installation of required support measures
e) installation of facilities at the surface
f) quality control for workmanship and material.

The Scope of Work is defined for the Diversion Tunnel at the connection area of the tunnel with the outlet and the intake structure during the excavation and support period.

1.3 Definitions

The basic definitions given in this TS are in conformity with the relevant standards in force.

1.3.1 DEWATERING SHAFTS

For the dewatering of the Diversion Tunnel, five shafts will be provided at the low point of the tunnel. The shafts will be running from the surface to the crown of the tunnel. Their length will be approximately 129 m and their inside diameter will be 750 mm. Coated steel pipes will be used as casing. For the dewatering procedure, pumps with flexible hoses will be installed in the individual shafts. The water collected in the Diversion Tunnel will be pumped via the shafts into a water collection sump, with a diameter of 3,050 mm, which will be located next to the shaft top structure. From there the water will flow through a HDPE pipe, with a diameter of 1,000 mm, to Canal 2. Details are given in the corresponding Drawing.
1.3.2 **SHAFT TOP STRUCTURE**

At the shaft tops, the steel pipes are founded with rectangular concrete slabs, flexibly bedded on the ground. These pipes are covered with blind flanges, equipped with a vent with screen. Details are given in the corresponding Drawings.

1.3.3 **PUMP SUMP**

At the bottom of the Diversion Tunnel, a 2.0 m x 2.0 m x 2.0 m pump sump will be installed. To accommodate this pump sump, the tunnel will be deepened, covering an area 6.0 m in length x 4.0 m in width. The invert will be made of cast-in-place, reinforced concrete with a minimum thickness of the required final lining thickness.

The pump sump will be covered with a fixed and perforated cover construction, which can be removed.

1.3.4 **SHAFT EXCAVATION OVERBURDEN**

The overburden material is described as soil. Therefore the shaft excavation in this layer will be done from the surface. The excavated hole, will be covered with a casing pipe, which will be advanced simultaneous to the drilling. The excavation diameter will be 1,050 mm. The casing pipe will be removed while filling the annulus between the final steel pipe and the borehole surface with cement-sand grout.

1.3.5 **SHAFT EXCAVATION ROCK MASS**

In the hard rock area, the shafts will be excavated adopting the raise-boring method. With this method, a pilot hole is drilled from the surface or the top end. At the low point of the borehole in the tunnel cross-section, a reamer with the required excavation diameter is connected to the drill rod and the excavation is done by pulling the rotating reamer back to the surface. The excavated material which falls into the tunnel can then be mucked out.

1.3.6 **FINAL CASING**

The final casing will be made of coated steel pipes with a wall thickness between 8 mm and 30 mm. The inside diameter will be 750 mm. The steel pipes will be coated on the interior and the exterior in compliance with the surrounding conditions. At defined distances, steel spacers will be provided at the pipe outside to keep the pipe string centric and to transfer the vertical loads to the surrounding rock mass.

The coating material requirements are specified below.

1.4 **General Work Requirements**

The Contractor shall be responsible for the quality of material and workmanship and for their conformity with the Design Documentation, other corresponding Specifications and Method Statements and the Engineer's instructions.
The Contractor shall provide his personnel with the entire equipment necessary in accordance with the Specification and shall grant them access to the works to enable them to carry out their work in a safe and proper way.

Before commencing the works, the Contractor shall propose a concept to the Engineer for approval. The concept shall comprise the equipment envisaged, the scope of work and the work stages.

2. Materials

2.1 Steel
The steel of the pipes shall be a high-quality steel in accordance with the C.S.A. Standards. Its characteristic yield strength shall not be lower than 240 MPa.

The spacers shall be of the same quality as the pipes and shall be factory-welded onto the pipe segment.

2.2 Coating
The installed steel pipes will be coated
On the exterior: with a 3-layer polyethylene (PE) coating
On the interior: with a fusion-bonded epoxy coating

The coatings will generally be factory-applied, yet the coating at the welded segment joints will be completed on site.

2.3 Annular Grouting Material
The annular grouting material shall be made of sand, cement and water, using approximately two parts of sand, one part of cement and one part of water. The detailed composition shall be adjusted by trials.

2.4 Concrete
The concrete for the concrete slab at the top of the shafts shall be a grade C2 quality according to the C.S.A. Standard A23.1-00.

The concrete for the pump sump shall be of the same quality and specification as the concrete for the invert segment. Reference is made to the corresponding “Concrete works, invert segment” Specification.
3. **Equipment**

The works may be performed using any type of equipment approved by the Engineer. The entire equipment must have a valid quality control certificate and is to be inspected and maintained within regular inspection and maintenance periods.

3.1 **Overburden Excavation**

For the overburden excavation, standardized equipment for shaft excavation of this diameter will be used.

3.2 **Raise Boring Equipment**

The equipment will comprise the following components (example):

- **Machine:** Tamrock Rhino 1000DC.
  - Weight: 14,000 kg (with crawler 18,000 kg).
  - Height: 5,450 mm (with beams 5,800 mm)
- **Stabilizers:** 11'"-12 ¼" integral stabilizers
- **Drill rods:** 10", 1.52 meter long (high strength)
- **Pilot bit:** 11" – 12 ¼" tricone roller bit (Sandvik or Baker Hughes)
- **Reamer head:** Sandvik CRH 3, weight (total): 2,600 kg
- **Cutters:** Sandvik CMR-41 and CMR-52

3.3 **Pipe Installation**

For the pipe installation, standardized equipment for this kind of pipe installation will be used.

4. **Transport**

All components shall be transported by suitable means of transport and in accordance with industrial safety and road traffic regulations to avoid any damage.

5. **Workmanship**

5.1 **Drilling and Casing in Overburden**

The drilling and casing of the borehole will be carried out simultaneously from the surface. Because of the water sensitivity of the surrounding soil material, water-base mud will have to be avoided.
The casing will be removed, while filling the annulus with the sand-cement-grout composition.

5.2 Raise Boring

5.2.1 SET-UP

1. An unarmored concrete slab, 5 m x 4 m x 0.25 m (length x width x height) is cast on an air-cleaned and well-leveled rock surface. The clearance height above the concrete slab shall be >6.5 m.

2. Two foundation beams are placed and positioned on the concrete slab. Each beam is held by twelve anchor bolts, diameter 20 mm - 25 mm with a length of 1600 mm, grouted into solid rock.

3. The raise borer is mounted on the beams and erected. The initial drilling direction is adjusted in one direction with the help of adjustable spanners and in the other direction with the help of shims placed between the foundation beams and the concrete slab.

4. A water re-circulation basin of 50 m³ at a minimum, is built adjacent (within 30 meters) to the drill site with double 4” steel pipes connecting the basin with the raise boring rig.

5. Before starting the pilot hole drilling, the initial drilling direction is controlled and all anchor bolts are tightened.

5.2.2 PILOT HOLE DRILLING

1. The pilot hole drilling commences slowly and carefully with low load and rotation.

2. Upon completion of the first stabilizer, the initial drilling direction is controlled by Skansa and the Cient (in special occasions) and adjustments are made - if necessary.

3. The pilot hole drilling continues, by adding one stabilizer to each other, carefully until the whole stabilizer package has been drilled into the rock.

4. The pilot hole drilling continues with normal load and rotation by adding one drill rod after another. Rock samples, coming up with the flush water, can regularly be taken for tests or inspections. If fractures or significant changes of the rock conditions are recognized, the thrust and rotation of the pilot bit is adjusted in line with our experience. If the flush water disappears, grouting may be necessary. (In case of Directional Drilling: values from the directional drilling tool are continuously displayed on a laptop computer in the operator’s cabin, and saved on disc.)

5. Once the pilot hole has reached its final depth, the deviation from the theoretical point of breakthrough will be measured.

5.2.3 CHANGING OF DRILL BIT FROM PILOT BIT TO REAMER HEAD

1. After breakthrough, the pilot bit will be dismantled and the reamer head will be connected.

2. The reamer will be taken down to the lower tunnel and put in the right position to be mounted.
3. Once put in the right position, the threads will be connected and fully torqued. At this point, the reamer must be locked, for example with the help of the machinery available inside the tunnel.

5.2.4 UP-REAMING TO FINAL RAISE BORE DIAMETER

1. The reaming phase commences from the bottom upwards, first carefully until the reamer head has full contact with the rock surface and then at normal load and rotation. The thrust and rotation will be adjusted, from time to time, in line with the experience acquired and the rock conditions encountered.

2. The cuttings produced by reaming will consist of fine material. The material will fall down through the shaft and pile up at the bottom where mucking is carried out.

3. When the reamer head will have reached the machine, it will be secured with chains and the machine will be de-mobilized. The reamer head will then easily be lifted out of the hole with a crane or a similar device.

5.3 Pipe Installation

The pipe string will be composed of prefabricated segments welded together on site. The steel thickness requires the welding method to be adopted. The welded joints shall have the same bearing capacity as the regular pipe walls. At the joints, the coating is completed on site.

The pipe string will be installed from the surface connecting the pipe segments and driving the string into the borehole all the way to the bottom.

After installation of the pipe string, the annular space will be grouted with the required grout composition. At last the pipes will be covered with blind flanges and the shaft top construction will be completed.

6. Quality Control

All components must have a valid quality certificate and a valid permission for the intended use.

6.1 Quality Test

All materials and components have to be tested for their specific use. Records of the testing shall be produced and submitted to the Engineer for approval. If necessary, adaptations of materials and components have to be made.

Quality tests of all delivered materials have to be carried out regularly. The equipment has to be inspected and maintained periodically to prevent failure during operation.

6.2 Control of Workmanship – General

All kinds of specified works have to be controlled and supervised for their adequacy according to the design and other method statements and specifications. The works shall be recorded daily,
furnishing information on progress, name of responsible people, number of workmen, used equipment, unforeseen events, etc.

6.3 Control of Workmanship – Raise Boring

6.3.1 RECORDS

1. For all works, a diary shall be kept on a day to day basis, describing activities, progress, notes, etc..

2. In addition, a drill record shall be produced when drilling. This record shall document the drilling characteristics for each drill rod, including such information as rod no., type of drilling (pilot hole or reaming), date (year, month, day), start time (hour, minute), stop time (hour, minute), load (metric tones), penetration (meter per hour), accumulated bored length (meter) incl. average length (value of directional drilling tool)

All records will be available to the Engineer's checking and approval.

6.3.2 CONTROL PROCEDURES

Prior to commencement of drilling works

The position and the alignment of the raise borer is controlled and documented in the diary. The tightening of all anchor bolts, holding the raise borer, is controlled.

During performance of drilling works

Upon completion of the first stabilizer, the initial drilling direction is controlled and documented in the diary (adjusted - if necessary). All drilling parameters (load, RPM, etc.) are continuously controlled (by the operator) and adjusted to the actual drilling situation. The parameters for each drill rod are to be noted down in the drill record. The rock cuttings are collected by the operator for visual inspection or test.

Upon completion of drilling works for pilot hole

Upon completion of the drilling works for the pilot hole, the final position and the length of the pilot hole will be measured and the results will be added to the diary.

6.4 Control of Workmanship – Annular Grouting

The success achieved by annular grouting has to be evaluated by recording the grout volume, the grouting pressure, and the grouting time. The values obtained have to be compared with the values calculated based on theoretical conditions.

7. Measurements

The quantity survey unit of the excavation shall be m³ excavated material. The quantity survey unit of the installed pipes shall be m.
8. **Acceptance**

8.1 **Conformity of Work with Design and Technical Specification**

The works shall be carried out in accordance with the design, the Technical Specification(s) and the written instructions of the Engineer.

8.2 **Acceptance of Works To Be Removed or Covered**

8.2.1 **DOCUMENTS AND DATA**

The acceptance of works to be removed or covered shall be based upon:

- a written statement by the Engineer entered into the Site Book that the works have been executed in accordance with the design and with the Technical Specification(s),
- other written statements by the Engineer commenting on the execution of the works.

8.2.2 **SCOPE OF WORKS**

The scope of works to be removed or covered shall be determined by written statements of the Engineer and by other documents confirmed by the Engineer.

9. **Applicable Regulations**

9.1 **Standards**

Canadian Standards

European Standards

***
Appendix 1.1(vv) - Owner’s Mandatory Requirements

1. GENERAL

1.1 Introduction

1. The Mandatory Requirements cover the minimum requirements for the design, instrumentation, construction, testing, commissioning and other requirements necessary for the performance of the Work. These requirements are the minimum acceptable requirements for the Work. The Contractor shall develop additional requirements and Specifications as necessary to perform the Work.

2. These requirements shall be used in conjunction with the Summary of Work, Concept Drawings and other information as provided by the Owner to perform the Work.

1.2 Operating Environment

1. The tunnel and all ancillary equipment required for its safe operation shall be capable of adequate operation under all weather and river conditions.

1.3 Water Surface Elevations

1. Water surface elevations defined in Appendix 1.1(sss) shall be used in the design of the Tunnel Facility Project as appropriate.

1.4 Water Level Gauges

1. The water level gauges for measuring the intake and outlet canal water levels are as shown on the Concept Drawings.

2. These gauge locations shall be used in conjunction with the hydraulic design levels defined in Appendix 1.1(aa) for determining the GFA of the tunnel.

1.5 Design and Service Life

1. The primary elements of the Niagara Tunnel Facility Project are required to be designed and constructed for a service life of 90 -yrs with no tunnel outages during such 90-yr life. Elements not specifically required to be designed to a 90-yr service life shall be designed to applicable and appropriate codes, guidelines and standards that are commensurate with their intended purpose.

2. The following elements shall be designed and constructed to a 90-yr service life:

(a) tunnel lining system, including

   (i) reinforced concrete lining

   (ii) annular grout
(iii) impermeable liner if used
(iv) gaskets and/or any other water control features incorporated in the Work

(b) intake structure
(c) outlet structure.

3. Assessment of 90-Yr Service Life

(a) **Loading** – The tunnel lining system and intake and outlet structures shall be designed for all short- and long-term prescribed time-dependent loading and deformations. The 90-yr service life shall be deemed to have been met by demonstrating compliance with the long-term time-dependent loading and deformations prescribed in Section 8.3 of this Appendix.

(b) **Loading and Deformation** – Compressible annular grout, if proposed, and compressible materials at the intake and outlet structures shall be designed to accommodate all short- and long-term time dependent loading and deformation as prescribed in Section 8.3. Confined compressive testing of annular grout mixes with a confining pressure equivalent to the applied pressure shall be performed to determine the compressive strength of the grout at the calculated long-term (90-yr) deformation. The 90-yr service life shall be deemed to have been met by demonstrating through testing that the measured compressive strength of the grout at a strain equivalent to the 90-yr deformation assumed for the design is greater than the ultimate design strength ($f_{c'}$) of the grout.

(c) **Sulphate Attack** – The cement for the annular grout and reinforced concrete lining shall be designed to resist the effects of sulphate attack. Accelerated tests shall be performed on the annular grout and lining concrete mixes. The 90-yr service life shall be deemed to have been met by demonstrating through testing that the mixes are resistant to sulphate attack derived from the highest values of sulphate concentrations for the groundwater in contact or potentially in contact with the tunnel lining or annular grout over a 90-yr period.

(d) **Corrosion from Chloride Penetration** – The tunnel lining system shall be designed to be resistant to corrosion from chloride penetration. The 90-yr service life shall be deemed to have been met by demonstrating that the time taken to reach the corrosion threshold at the reinforcing steel, based on chloride diffusion rates for the concrete and chloride levels present in the groundwater in contact or potentially in contact with the tunnel lining or annular grout, exceeds 90 years. Tests to derive chloride diffusion rates used to demonstrate compliance with 90-yr service life shall be in accordance with test methods in accordance with the Nordtest Method, NT Build 443 (Approved 1995-11), Nordic Innovations Centre, or as otherwise approved by the Owner.
(e) **Abrasion** – Concrete in water passages shall be designed to be resistant to the abrasive action of water flow, entrained ice and debris. For this purpose, concrete in water passages shall be dense, have a low water/cement ratio and be of sufficient strength. Precedents in projects of similar conditions shall be used to establish the required concrete material properties and to assess compliance with the 90-yr service life.

### 1.6 Safety by Design

1. Design methods consistent with the ‘Safety by Design’ approach shall be used.

### 1.7 Equipment Isolation and Interlocks

1. All equipment that can instantaneously release dangerous amounts of energy to personnel maintaining the equipment shall be fitted with adequate isolation devices and lockout mechanism as required by the Owner.

2. Electrical breakers must be lockable in open and closed positions and must have visible contacts (Visibreak). Valves must be lockable in open and closed positions.

3. All safeguarding devices (interlocks) that signal equipment to stop shall comply with the appropriate Canadian Standards Association, American National Standards Institute, International Organization for Standardization or European Norm. The Contractor shall provide documentation to the Owner certifying that all such safeguarding devices have been manufactured and installed in accordance with manufacturer’s instructions and that the protective devices have been manufactured or modified to meet current applicable standards.

4. For all other safeguarding devices, the Contractor shall provide documentation to the Owner certifying that the protective element is installed in accordance with the manufacturer’s instructions and current applicable standards.

### 1.8 Dam Safety

1. The outlet closure gate equipment will be tested for operation by the Owner at a minimum once yearly after Final Completion Date. For this purpose, the gate equipment shall be capable of being operated over any partial range within its full range of operation.

### 1.9 Condition Surveys

1. Pre-construction and post-construction condition surveys shall be undertaken by the Owner of all buildings and infrastructure including any active recorded drinking water wells within 300 m of the construction works, including but not limited to the INCW, the PGS station and dykes, and third party properties. Independent consultants, qualified in this work, will carry out the condition surveys. The Contractor shall review and accept the results of these surveys. These surveys will be
used to determine the impact, if any, of the performance of the Work on the surveyed buildings and infrastructure.

2. **ENVIRONMENTAL PROTECTION**

2.1 **General**

1. As they relate to the performance of the Work, the Contractor shall be responsible for
   
   (a) compliance with the EA and the EA Approval, and for fulfilling all associated EA Approval conditions; and
   
   (b) compliance with Department of Fisheries and Oceans Authorization 5250-43.

2. All necessary Approvals shall be in place prior to undertaking the relevant element of Work.

2.2 **Minimum Requirements**

1. The Woodlands Reserve Area and meadow identified on the Concept Drawings shall be protected with fencing paid for and installed by the Contractor. Trespassing within these areas by Contractor Personnel is not permitted.

2. Trees to be cut shall be flagged and shall only be cut after approval by the Owner.

3. On-Site burning shall not be allowed.

4. Tree clearing and grubbing shall not occur between May 1 and June 15 to avoid the main bird nesting and raising period, unless approved by the Owner.

5. The Contractor shall demonstrate, through testing, that the areas where the “contaminants” (as defined under the *Environmental Protection Act (Ontario)*) were stored have been remediated to meet the soil, groundwater and sediment standards of Regulation 153/04, Environmental Protection Act (Ontario), for non-potable groundwater criteria for industrial land use sites, as more particularly set out in Table 3 of MOE publication entitled “Soil, Groundwater and Sediment Standards for Use Under Part XV.I of the *Environmental Protection Act (Ontario).*”

6. If fuelling facilities are required on Site, there shall be only one such fuel facility located at the outlet work area. The fuel tanks shall be stored above ground on a concrete pad and shall comply with Technical Standards and Safety Authority Liquid Fuels Handling Code.

7. Sewage holding tank(s) shall be installed to average the flow rates prior to sewage disposal into the City of Niagara Falls sanitary sewer.

8. The Contractor shall take all necessary measures to ensure that hourly equivalent sound levels from construction activities are met at sensitive receptors in accordance
with MOE Publication NPC 205, unless written exceptions have otherwise been obtained.

9. Construction equipment and trucks shall meet the requirements of MOE Publications NPC 115 and 118. They shall be measured at a distance of 7 m (15 m for tracked drills and heavy trucks) according to the standards and procedures prescribed in MOE Publication NPC 103 to confirm their compliance. Measurements shall take place before the equipment is used and annually thereafter. For new equipment where manufacturer’s data are available, the first measurement may be waived.

10. Blasting

(a) All blasting shall be undertaken in compliance with NPC 119 as applicable unless exceptions obtained.

(b) The Contractor shall establish standard blast warning codes.

(c) Notice of blasting shall be placed in local newspapers. The Contractor shall develop and submit a protocol for informing immediately affected residents, Niagara Parks Commission, Niagara Helicopters, OPG, Hydro One, Niagara Falls Bridge Commission, City of Niagara Falls and Town of Niagara-on-the-Lake of the blasting schedule.

(d) Monitoring of all ground vibrations shall be undertaken during all blasting, with special emphasis on the INCW structure, the PGS dyke and the PGS generating station. The peak particle velocity shall be monitored at all structures with the peak ground acceleration also monitored at the downstream toe of the PGS dyke at its closest proximity to the outlet canal excavation. The Contractor shall make his own assessment of the effects on blasting on structures and establish appropriate limits; however, the limits defined in the following table shall not be exceeded.

Limits on Blast Vibrations

<table>
<thead>
<tr>
<th>Measurement</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Peak Partical Velocity (at structure)</td>
<td>&lt;30 mm/s</td>
</tr>
<tr>
<td>Acceleration, 2/3 Peak Value (at toe of PGS dyke)</td>
<td>0.04 g</td>
</tr>
</tbody>
</table>

(e) All blasting material shall be stored in a designated magazine building which shall be securely locked at all times. A weekly audit of blasting material shall be made and reconciled with blasting materials actually used at the Site. The Contractor shall notify the Owner immediately of any missing blasting material.
(f) The Contractor shall comply with DFO Authorization 5250-43 issued under Section 32 of the Fisheries Act for underwater blasting.

3. **DISPOSAL OF EXCAVATED MATERIAL**

1. The Contractor shall provide a temporary storage pad in the main construction facilities area for holding any excavated material suspected of being contaminated (including formations containing benzene, toluene, ethyl-benzene and xylene). Such materials will be stored until the results of chemical testing are available to determine how the material is to be managed and disposed of to the Approval of the Governmental Authorities having jurisdiction. The storage pad shall have an impermeable base and shall be surrounded by peripheral drains/ditches to capture any runoff. The runoff shall be suitably treated prior to discharge. The storage pad shall be of sufficient size to hold a minimum of 15 working days of excavated material.

2. Where a surge pile or stockpile is provided at the outlet area, including the stockpile at the designated disposal area, any runoff from the surge pile or stockpile shall be directed to a Contractor-supplied water treatment facility that has Approvals prior to discharge into any watercourse.

3. Methods of depositing of material in the stockpile shall ensure good compaction with side slopes, such that the surface provides sufficient slope for drainage at all times, and any ponding of water on the surface does not be occur. The stockpile shall be designed and constructed to be permanently stable on the underlying foundation material with side slopes not steeper than two horizontal to one vertical.

4. At completion of the Work, the Contractor shall ensure that the surface of the stockpile is generally level, such that the difference in elevation over any part of the stockpile shall not exceed 1 m, and the surface shall be graded smooth and crowned sufficiently so as to drain to the edges of the stockpile. The toe of the stockpile shall not encroach on any elevation lower than 180 m, unless approved in writing by the Owner, and shall be no closer than the distance specified on the Concept Drawings to the edge of the existing canals. Stock piles will be revegetated to reduce long-term erosion.

5. The Contractor shall ensure that its stockpiling operations at the disposal area does not cause damage, or limit the Owner’s access, to the existing transmission line that is located on the southern edge of the stockpile area. The toe of the stockpile shall be no closer than 5 m from any part of the structure of the towers, or of the location in plan of the overhead lines.

6. The Contractor is required to sample excavated material to determine if contaminants have been introduced by the Contractor during the course of the work. Any material found to be contaminated shall be segregated and treated by the Contractor prior to being delivered to the disposal site.

7. Excavated rock suitable for aggregate production shall be disposed off-site in accordance with Applicable Laws and in a manner to facilitate its use as aggregate.
8. No excavated material shall be spilled into a watercourse.

4. **TUNNEL, INTAKE AND OUTLET ALIGNMENT**

4.1 **Tunnel Alignment**

4.1.1 **Alignment Constraints**

1. The alignment of the tunnel shall satisfy the following requirements:

   (a) the submerged intake of the tunnel shall be located beneath Gate 1 of the INCW at the location and orientation indicated on the Concept Drawings

   (b) the outlet structure of the tunnel shall be located on the northwest side of the SAB2 Canal at the location and at the azimuth indicated on the Concept Drawings

   (c) the horizontal alignment of the tunnel shall remain within the subsurface right of way as indicated on the Concept Drawings. The vertical alignment indicated on the Concept Drawings was the basis for the EA Approval. Deviation from this vertical alignment, indicated on the Concept Drawings, may require an amendment to the EA. The Contractor shall be responsible for obtaining such an amendment.

   (d) the tunnel alignment shall not preclude future construction of a similarly designed tunnel with an intake beneath Gate 4 of the INCW and an outlet structure parallel and located south of the new tunnel outlet structure

   (e) the tunnel alignment shall be such as not to cause a material change in the in-situ stress regime at the existing tunnels or the Toronto Power Generation Station wheel pit as determined by numerical analyses such as PHASE2 or equivalent

   (f) a dewatering station shall be provided at the low point of the tunnel. The shafts shall be located on the Owner’s land east of the buried St. Davids Gorge.

5. **INSTRUMENTATION**

5.1 **Purpose**

1. Instrumentation during tunnel construction shall be installed and monitored until Final Completion by the Contractor, as required, to

   (a) monitor movements of existing structures and buildings affected by the Work to ensure their protection, structural integrity and safety
(b) monitor the tunnel and response of adjacent rock at a single section to be selected by the Owner during construction, filling and commissioning

(c) monitor response of initial lining to the imposed rock loading at locations as required on the basis of observations during tunneling

(d) monitor groundwater piezometers around the tunnel.

2. Standpipe tunnel piezometers to monitor the tunnel piezometric during tunnel operation.

5.2 Instrument Type

1. Surface movement monitoring point (SMMP)-A surface movement monitoring point is a marker fixed to a surface, and used for the measurement of the vertical and horizontal movements of that surface. SMMP shall be permanent pins on structures or grouted rods in rock. Survey equipment (theodolite, level, electronic distance measuring device, tape extensometer), shall be capable of measuring vertical and horizontal movements of the SMMPs to ±1 mm.

2. Multiple Point Borehole Extensometers (MPBE)-A multiple point borehole extensometer is a device installed in boreholes for monitoring the changing distance between more than two points along the axis of the borehole. The MPBE shall be of the vibrating wire type and shall be capable of determining the relative position of each anchor to the surface installation with a repeatability of ±0.1 mm.

3. Groundwater Piezometer-A groundwater piezometer is a device that is sealed within the ground so that it responds only to groundwater pressures around itself. Piezometers shall be of the vibrating wire type and shall be capable of measuring the head of water at the piezometer tip to a repeatability of ±0.1 m.

5.3 Minimum Instrumentation Requirements

5.3.1. Surface Movement Monitoring

1. Install SMMP on masonry or buildings prior to commencing any excavation. Buildings shall include, but not be limited to, INCW structure Bays 1 to 5 and the INCW control and maintenance buildings.

2. Install a series of SMMPs on the INCW structure on Bays 1 to 3 above the intake excavation with a spacing of no more than 5 m.

3. Install SMMP’s at the pier nose of Piers 1 and 2.

4. Install a plumbline at the pier nose of Piers 1 and 2 extending to rock level. The plumbline shall have measuring tables at least three locations.

5.3.2. Excavation Monitoring
1. Install a permanent array of a minimum of one MPBE on each vertical or near vertical rock cut at the intake and outlet structures at approximately the midpoint that shall have, as a minimum, monitoring positions (anchors) at 20, 10, 5 and 2 m from the wall of the excavation. Electrical leads shall be in watertight conduits leading to a lockable watertight box located at the deck level.

2. Monitor tunnel convergence following installation of the primary lining by tape extensometer or survey methods repeatable to ±1 mm as required, dependent on response to imposed rock loads. Number and locations of monitored sections shall be agreed with the Owner.

5.3.3. Instrumented Tunnel Section

1. The following instrumentation shall be installed at one section of the tunnel as selected by the Owner:

(a) install a permanent array of a minimum of eight MPBEs that shall have, as a minimum, monitoring positions (anchors) at 25, 10, 5, 2 and 1 m radially from the inside surface of the tunnel lining. Installation shall be completed and the initial readings taken before the tunnel face advances more than 25 m beyond the array. This array of MPBE shall be capable of being monitored remotely from the surface during the initial filling and operation of the tunnel.

(b) install a permanent array of a minimum of six piezometers around the exterior of the tunnel lining and one on the interior of the lining at the tunnel invert. The array of piezometers shall be capable of being remotely monitored from the surface during the initial filling and operation of the tunnel.

(c) electrical leads for MPBEs and piezometers shall be in watertight conduits, adequately fixed to the tunnel crown and extending up one of the dewatering shafts leading to a lockable watertight box located at the top of the shaft.

5.3.4. Tunnel Standpipe Piezometers

1. Tunnel piezometric levels shall be measured at two locations along the alignment of the tunnel at approximate chainages 30+00 m and 90+00 m. Each location shall consist of two standpipe piezometers, 2 to 20 m apart, extending through the tunnel lining at the tunnel crown to the ground surface. Final locations shall be agreed with the Owner prior to installation.

2. Piezometer holes shall be cased with a corrosion resistant casing with a minimum 95 mm inside diameter. The annular gap between the rock and the casing shall be grouted to prevent groundwater migration between the different rock formations.

3. Detailing of the piezometer fitting at the tunnel crown shall ensure that the velocity head is not measured and that degradation of the adjacent tunnel lining or fitting does not occur. The fitting shall be corrosion resistant.
4. The piezometer shall be embedded in concrete at the surface with adequate detailing to prevent problems of ground movement due to frost heave. A watertight, lockable cap shall be provided.

5. Arrangement of piezometers shall be consistent with flow verification requirements.

6. **STRUCTURES AND EXCAVATIONS**

6.1 **General**

1. The Contractor shall establish all design parameters, load cases and load combinations as required by Applicable Laws, codes, standards and guidelines, this Agreement and as necessary for the design and construction of structures fit for their intended purpose, robust, reliable and maintainable, with adequate safety factors and detailed to deal with all conditions throughout their required 90-yr service life. Normal, unusual and extreme conditions of loading shall be considered in determination of the design loads.

6.2 **Stability**

1. Stability of the structures shall be checked using the limit equilibrium method using guidelines outlined by the United States Bureau of Reclamation or the Corps of Engineers. Load cases shall be developed in the most critical combinations and adequate factors of safety against sliding, uplift, overturning, including base stresses, provided.

2. Passive pressures due to backfill shall not be considered.

3. The weight of rock in a mobilized wedge above the structure shall only be considered in the calculation of uplift stability.

4. Cohesion at the concrete rock interface shall not be assumed.

5. Rock anchors shall not be used to provide the required stability of gravity structures.

6. The stability of the excavations shall be evaluated and provision shall be made in the design for rock support to be installed as identified in the stability evaluation. The evaluation and design of the excavation shall take into consideration the requirements for

   (a) the stability of the INCW

   (b) permanent stability conditions of the vertical faces.

7. Permanent rock support systems, where required, shall be provided with suitable corrosion protection.
6.3 Effects on Existing Structures

1. The Contractor shall investigate the effects of tunnel construction on existing structures, including, but not necessarily limited to,

   (a) the effects of deformation on equipment operation including the INCW gates
   (b) the effects on structural strength and integrity
   (c) the effects on structural stability.

6.4 Excavation

1. The sides of the intake channel and outlet canal excavations shall be line drilled and controlled blasting techniques employed to ensure that the rock beyond the excavation limits is not damaged or destabilized by the blasting operation. Any damaged rock shall be removed and backfilled with concrete adequately tied back to sound rock to produce the requisite excavation lines.

2. Due to the need for blasting at close proximity to the INCW, preset rock reinforcement may be required to be provided prior to excavating for the intake to secure the integrity of the foundation of the control structure.

3. During excavation, methods shall be employed to prevent damage to existing structures and buildings and to prevent detrimental effects to the operation of existing equipment. Blasting velocities shall be carefully controlled and monitored to ensure adequate control.

4. Any exposed shaly rocks or shale layers which are susceptible to deterioration upon exposure to wetting and drying cycles and large temperature differences shall be immediately protected by shotcrete.

6.4.1 Outlet Canal Rock Plug Removal

1. The outlet gate shall be closed and under balanced water conditions during rock plug removal.

2. Excavated material shall be removed from the PGS canal prior to the PGS canal being brought back into operation.

3. A sounding survey of the PGS canal shall be performed before and after removal of the rock plug to verify that no excavated material remains within the PGS canal and the results submitted to the Owner.

4. No material shall be allowed to be carried down the PGS canal during and after removal of the rock plug.
6.5 Intake Structure, Intake Channel and Intake Approach and Accelerating Walls

1. The location and dimensional geometry of the intake channel and intake approach wall are fixed as defined on the Concept Drawings as adjusted for final tunnel slope and diameter. The alignment and dimensional geometry of the ice accelerating wall is generally as shown on the Concept Drawings. The intake channel, ice accelerating and approach walls shall be designed and constructed to convey water smoothly into the intake structure and shall provide satisfactory performance for both open water and ice conditions.

2. The intake structure location, internal dimensional geometry, and transition from the shape at the entrance to the circular shape of the tunnel are fixed as defined on the Concept Drawings. Adjustment to the geometry for tunnel diameter or tunnel slope shall be as indicated on the Concept Drawings.

3. The intake and outlet structures shall be designed and detailed with an appropriate compressible material or other means to accommodate a minimum of 100-mm movement due to time-dependent deformations of the rock.

4. Suitable venting shall be provided at the intake behind the sectional gate to permit aeration of the tunnel during filling and dewatering. Vent sizing shall be such as to limit noise levels during filling and dewatering to the relevant noise restrictions.

5. A cover shall be provided over the top of the sectional service gate openings in the intake structure to avoid the possibility of ice being drawn into the structure. The cover shall be of ample mass to prevent dislodgement and shall be detailed to prevent seizing of the cover after prolonged submergence. Appropriate lifting devices shall be provided on the covers to enable the sectional service gate follower to engage and lift the gate slot cover.

6. The intake approach wall shall be blended into the existing SAB2 intake wall.

7. The accelerating and intake approach walls shall be adequately capped with concrete.

8. The Contractor shall
   
   (a) provide the facility for bubbling along the river side of the cofferdam in the event that ice starts to form along the cofferdam or sticks to its walls;

   (b) design and construct the cofferdam to minimize impact on flow at the INCW; and

   (c) remove the existing ice accelerating wall and construct the new wall prior to construction of the cofferdam at the intake.
6.6 Dewatering System Shafts

1. Each shaft shall be circular, with a minimum internal diameter of 1.05 m in overburden and 0.915 m in rock to accommodate the Owner’s pumping equipment and arrangement. The shafts shall be located on the centreline of the tunnel so that the pumps can be positioned over the tunnel invert. One sump shall be provided at the invert below one of the dewatering shaft locations such that a submersible pump can be positioned below the tunnel invert to achieve the required operating submergence in the final stage of dewatering.

2. The shafts shall be capped for normal operation of the tunnel and the cap shall be protected from pressure surges with air vents.

3. The dewatering shafts shall be lined in the overburden section with a corrosion resistant sleeve.

4. The rock portion of the dewatering shafts shall also be lined with a corrosion resistant sleeve and the annulus between rock and sleeve grouted to prevent groundwater migration between different rock formations.

5. A sump shall be provided at the invert of the tunnel to allow the suction inlet of one pump to be lowered into the sump to provide the necessary operating submergence.

6.7 Demolition of Dewatering Structure

1. Means and methods used in demolition of the dewatering structure shall be such as to minimize impact on the operation of the PGS. Construction activities shall be coordinated with the Owner as indicated in Appendix 1.1(sss), Section 3.1(c).

2. The piers shall be removed flush with the sill. Abutment piers shall be retained; however, any loose sections of concrete shall be removed or tied back to sound rock.

3. Demolished materials shall be removed from the PGS canal. A sounding survey as required by Section 6.4.1.3) shall be performed. No demolished material shall be allowed to be carried down into any of the other existing canals.

4. The relocated waterline shall be constructed to the same standards and details as the existing waterline running over the dewatering structure. The waterline shall either be relocated to run across the PGS canal at the downstream deck of the PGS or near its existing location by means of a pipe bridge. The waterline shall be relocated and in operation prior to the start of demolition of the dewatering structure. The commissioning procedure shall minimize disruption of water supply. Commissioning shall be coordinated with the Owner.
7. INTAKE SECTIONAL SERVICE AND OUTLET CLOSURE GATES, HOISTS AND GUIDES

7.1 General

7.1.1. Intake and Sectional Service Gate

1. A sectional service gate shall be provided to isolate the tunnel from the upper Niagara River GIP at the INCW to facilitate dewatering by OPG. The service gate shall be installed under conditions of no flow when there is a requirement to dewater the tunnel. The top gate section shall be fitted with a manually actuated, non-hydraulic, equalizing valve to allow for equalizing the water pressure across the gate. The gate shall be removed under balanced head conditions once the tunnel is filled.

2. The sectional service gate shall be designed to be installed using mobile cranes situated on the INCW. Mobile crane loads shall be limited to the specified bridge capacity. Outriggers may be situated on the extended piers during lifting; however, outrigger loads shall not cause distress to the structure. Service gate sections shall be sized to match the mobile crane equipment at the required reach and arrangement.

3. The sectional service gate follower shall provide a means to engage and disengage from the gate or slot cover with control from the surface.

4. Removable gate extensions shall be provided to allow for installation of the gates from the surface using the gate follower. The structure to extend the guides shall be rigid enough for this purpose and be designed for gate jamming. The structure shall be fabricated in sections to allow for installation and removal to an off-site storage location. Suitable platforms shall be provided at the top of each guide extension to allow for personnel to guide the gates into place. Suitable handrails shall be provided. The structure may be installed with the use of divers; however, underwater work shall be limited and shall not require divers to manipulate heavy structures underwater.

7.1.2. Outlet Closure Gate

1. The gate shall be capable of safely opening and closing against head and flow conditions, and when closed, withstanding the hydrostatic pressure imposed by the maximum water level in the outlet canal while the tunnel is dewatered.

2. The gate shall be raised and lowered by a dedicated, fixed hoist mounted on a steel structure above the gate location. The hoist shall be designed to maintain the gate in the raised position without dogging. The gate shall have the capability of being dogged in the open position to permit hoist maintenance.

3. The gate shall be articulated and allow the top section to be lifted enabling watering up of the tunnel.
4. Capability for installation and removal of a sectional service gate using a mobile crane operating from the wall of the outlet structure in the future shall be provided for in the layout and design of the structure.

7.2 Design Requirements

7.2.1. Loads and Load Combinations

1. The Contractor shall establish all design parameters, load cases and load combinations as required by Applicable Laws, codes, standards and guidelines and as indicated herein necessary for the design and construction of the gates, hoist and guides fit for their intended purpose, robust, reliable and maintainable, with adequate safety factors and detailed to deal with all conditions throughout its required design life. Normal, unusual and extreme conditions of loading shall be considered in determination of the design loads.

2. In particular, the following loads shall be considered in conjunction with other loads developed for the design of the gates, guides and hoist

   (a) hydrodynamic loading with the gate descending or ascending at applicable design speed for any position of the gate and including the effects of the maximum transient head in the tunnel during gate closure

   (b) structure weight

   (c) roller, seal, bearing bar and static and dynamic spring friction forces

   (d) impact loads of 30%

   (e) lateral loads of 30% of maximum loads acting normal to roller path

   (f) impact loads of 100% on lifting points and dogging devices

   (g) lateral loads acting in the plane of the bearing path generated by gate or steel sectional service gate flexure

   (h) loads due to wire rope hoists developing motor rated torque

   (i) loads caused by a jammed gate at any point in the guides, with locked rotor or motor stall torque, whichever is greater, 100% hoist efficiency and the force being applied to one lift point.

7.2.2. Materials

1. All sealing surfaces shall be stainless steel.

2. Gate roller paths shall be stainless steel.

7.2.3. Gate Hoist
1. The outlet closure gate fixed hoists shall be of the wire rope type and shall be designed to meet the following requirements:

   (a) each gate hoist shall be located in a weather-tight housing on the steel superstructure of the outlet structure

   (b) each hoist shall be equipped with sufficient protection (*e.g.*, limit switches, interlock) to prevent damage to the gate, the outlet structure and the hoist structure

   (c) control of each hoist shall be both local and remote

   (d) each hoist shall be capable of lowering the gate at the maximum speed allowable based on minimizing transient pressures in the tunnel

   (e) a fail-safe braking system shall be installed on each hoist for emergency controlled unpowered lowering of the gate

   (f) the hoist shall comprise two drums, driven through separate drive trains by a common double ended electric motor

   (g) the gate shall be held in the raised position by electrically operated brakes on the input shafts of each gear reducer

   (h) the gate speed for unpowered lowering shall be controlled by centrifugal fan brakes on the high speed shafts of each gear reducer

   (i) the following maximum hoist speeds shall be used

      (i)  Raising  0.16 m/min

      (ii) Lowering (Powered)  0.16 m/min

      (iii) Lowering (Unpowered)  0.31 m/min

7.2.4. Gate and Hoist Structural Components

1. For consistency with usual design practice, the working stress design method shall be applied, and AISC Specification for Structural Steel Buildings (ASD) and CSA Standard B167 shall be used.

2. Allowable stresses shall be based on those defined in AISC. A 3-mm allowance shall be made for corrosion. Design stresses for Normal Loading Conditions shall not exceed 90% of those permitted by AISC. For Extreme Loading Conditions allowable stresses may be increased by 33% provided they do not exceed 80% of the yield stress of the material. For hoist design, CSA Standard B167 should be referenced instead of AISC, but otherwise the same restrictions on allowable stresses shall apply.
3. Bolted connections shall be designed using high strength bolts in friction type connections, in accordance with AISC, except that design stresses shall not exceed 90% of those permitted by AISC.

4. Bolted connections must be watertight and shall have bolts at a suitable pitch. Seal welds shall not be used on bolted connections.

5. Maximum deflection of the gates under normal loading conditions shall be limited to 1/800 of the span between main rollers or bearing bars or one half allowable seal flexure at the seals, whichever is less.

6. All welded connections subject to immersion shall be seal welded.

7. Sufficient weight shall be provided in each gate and gate section so that it shall close readily under its own weight during normal hydraulic conditions. The lowering force shall exceed the resistance to lowering, based on static friction coefficients, by a minimum of 25%.

7.2.5. Mechanical Components

1. For normal conditions, design stresses shall not exceed those permitted by CMAA Specification 70, AISE Technical Report No. 6, and AGMA Standard 420.04.

2. For Extreme conditions, design stresses shall not exceed 80% of the elastic limit of the material.

3. The load on wire ropes shall not exceed 20% of the minimum breaking strength of the rope.

4. Main rollers shall be designed in accordance with the criteria outlined in ASCE Paper 3000 “Fixed Wheel Gates for Penstock Intakes” or approved equivalent. The exception shall be that the ‘Critical Stress’ obtained from the formula on Page 755 of ASCE Paper 3000 shall be multiplied by 0.30 for normal loading conditions and by 0.45 for extreme loading conditions to achieve suitable factors of safety.

5. The roller axles shall be designed in accordance with ASCE Paper 3000. The design of flat and crowned rollers and their supports shall take into consideration the rated radial load acting on the roller and an axial load equivalent to 30% of the radial load acting at the outer rim of the roller and the roller path.

6. The maximum shear stress (in MPa) in rollers and roller paths shall not exceed 2.40 times the minimum BHN of the softer material or 620 MPa, whichever is less.

7. The maximum compressive stress (in MPa) in rollers and roller paths shall not exceed 6.90 times the minimum BHN of the softer material or 1700 MPa, whichever is less.
8. The roller face shall have a surface hardness of 255 to 280 BHN. The minimum roller path hardness shall be at least 50 BHN greater than the minimum roller face hardness.

9. Crowned rollers shall use anti-friction bearings.

7.2.6. Gate Controls, Heating & Electrical

1. The hoist control shall automatically detect and compensate for any creeping of the gate toward the closed position.

2. A slack rope switch shall be furnished that detects rope slacking in the event that the gate hoist closes, but the gate hangs up.

3. Gate, hoist and guides shall be adequately heated to ensure reliable winter operation, and prevent icing of the gate to allow for remote position indication.

4. If the gate is in the open position it shall remain in the open position if power to the gate is interrupted.

5. Gate control shall be interconnected to the Owner’s existing plant control system.

6. Hoist motors to be TEFC, CEMA-MG-1, Section 2.

7. Electrical enclosures and junction boxes to be CEMA 4X, stainless steel.

8. Cabling to be steel armoured TECK FT1 with black outer neoprene.

7.2.7. Painting

1. Gate section shall be prepared and painted in accordance with OPG’s specification WIP — HO0386.

7.2.8. Maintainability

1. Components subject to wear or deterioration (e.g., bearings, seals, wire ropes) will require servicing and maintenance at regular intervals as recommended by the manufacturers or as dictated by observed conditions. Design and detailing of these components shall be such as to maximize ease of maintenance and minimize maintenance interventions.

2. The design and construction of all equipment and structures shall consider the following maintenance requirements:

   (a) personnel safeguards during all phases of the maintenance work

   (b) partial and full lowering of the outlet gate, once yearly to ensure proper operation
Appendix 1.1(vv) - Owner’s Mandatory Requirements - Page 19

(c) adequate access to all serviceable components
(d) provision for suitable lifting and handling equipment
(e) suitable spare parts to minimize downtime of all systems.

8. TUNNEL

8.1 General

1. The tunnel shall be capable of being dewatered within a specified time of 3 weeks and the tunnel lining shall be capable of resisting all internal and external loads that are anticipated during the service life of the diversion tunnel.

2. The tunnel lining system shall be designed, detailed, fabricated and constructed to deal with the highly corrosive environment that will exist along its alignment.

8.2 Hydraulic Design

1. The hydraulic conveyance system shall extend from intake structure at the GIP to the outlet water level gauge in the outlet canal and include the intake channel, intake structure, tunnel, outlet structure, and outlet canal to the point immediately upstream from the transition at the junction with the PGS channel.

2. The tunnel conveyance system shall be designed, detailed and constructed to provide the optimum hydraulic efficiency.

3. The tunnel shall be capable of delivering a GFA with the hydraulic head and energy grade design level defined in Appendix 1.1(aa) considering the hydraulic conveyance system defined in Section 8.2(1).

4. Transient load analysis shall be performed based on powered and unpowered closure rates for outlet gate and appropriate intake and outlet water levels.

5. Loads determined from the transient load analysis shall be used for input into the design of the outlet gate and structure and tunnel liner. The outlet surge shaft shall be sized to limit the transient load while retaining the upsurge water level within the confines of the shaft.

8.3 Tunnel Lining Design

8.3.1 General Considerations

1. Only the following design approaches are acceptable, individually or a combination thereof,

   (a) a tunnel lining system (either pre-cast or cast-in-place) capable of adequately supporting all loads including those imparted on the lining from long-term rock swelling effects
(b) a tunnel lining system which incorporates an impermeable liner so that long-
term rock swelling is prevented from developing.

The Contractor is to provide confirmatory analysis to support that its selected
approach meets the requirements of this Agreement.

2. The Contractor’s tunnel excavation and lining design may investigate all the above
approaches, with the following restriction:

(a) an impermeable lining system will not be acceptable as the sole design
approach, unless a testing method acceptable to the Owner is included to
prove that the constructed lining system is impermeable and will not allow the
passage of water or chloride ions.

3. Rock support systems shall be provided with suitable corrosion protection.

4. The tunnel lining shall be made of concrete and reinforced as necessary to control
cracking during construction and after installation, and to prevent overstressing at the
joints in the case of precast lining.

5. The tunnel lining shall be designed to be as watertight as practical under normal
operating conditions commensurate with the tunnel design approach.

8.3.2. Tunnel Lining Load Conditions

1. Internal hydrostatic pressure will correspond to the water surface level at the GIP and
the transient upsurge due to closure of the outlet gate.

2. Loads to be considered in the design of the concrete lining shall include, but not
limited to, the following:

(a) self-weight of the lining

(b) rock loading of a loosened slab of thickness not less than 3 m up to the full
width of the tunnel and shear deformations along bedding planes

(c) immediate elastic deformation of the rock mass

(d) elastoplastic deformations prior to filling of the tunnel

(e) grouting pressure

(f) external groundwater pressures prior to filling the tunnel

(g) loading resulting from stress changes caused by tunnel excavation

(h) time-dependent rock deformation loading on the lining
(i) internal hydrostatic pressure. Unbalanced hydrostatic pressure at the time the tunnel is filled. Additionally, pressure differential due to closure of the gate.

(j) thermal effects due to differential temperatures between lining and rock at time of installation and between lining and water

(k) full external groundwater pressures following dewatering of the tunnel unless a pressure relief system that is consistent with the selected tunnel lining system design, and acceptable to OPG at its sole discretion, is provided. In any case, the external pressure shall not be taken as less than 50% of the external groundwater pressure.

8.3.3. Load Combinations

1. Loads and load effects in Section 8.3.2 shall be considered in appropriate combinations and take into account the stages and sequences of construction and operation, and ground/structure interaction.

8.3.4. Numerical Modelling

1. The tunnel lining system shall be modeled by appropriate numerical methods. Closed-form solutions are not acceptable. The design shall account for the loads and loading conditions identified in Sections 8.3.2 and 8.3.3.

2. For portions of the tunnel in the Queenston Shale, modeling using FLAC or an equivalent numerical method acceptable to the Owner, is required.

(a) Considerations during analysis and design shall include, but not be limited to,

(i) the accessibility of the rock to freshwater (or high relative humidity) during construction and throughout the lifetime of the structure and the influence of bedding planes on freshwater access

(ii) the variability of the amount and rate of time-dependent deformation along the length of the tunnel and other structures

(iii) the effect of stress on rock swelling rate

(iv) the state of stress in the rock mass after excavation which affects the rate the swelling

(v) swell anisotropy

(vi) non-uniform loading.

(b) The modeling shall include

(i) analyses for both the deepest and shallowest tunnel sections in the Queenston formation
(ii) both unwatered and operational tunnel conditions.

(c) The following parameters shall be included in the analyses:

(i) appropriate rockmass and bedding plane strength and deformability values as given in the GBR

(ii) appropriate in situ stresses as given in the GBR

(iii) Hoek-Brown residual rock mass strength parameters: $m_r = 1.0$, $s_r = 0.001$ (or equivalent)

(iv) plastic shear strain in rock for peak to post-peak: ranging from 0.5% to 2.0%

(v) design line for rock swelling rates as shown in Figure 8.1 (maximum free swell potential of 0.3% per log cycle is based on overall average of all free swell test results)

(vi) time steps up to 4.5 log cycles of time in increments of days
(vii) rock mass permeability of $1 \times 10^{-6}$ cm$^2$/s in the plastic zone (after grouting)

(viii) chloride diffusion coefficient of $1.5 \times 10^{-6}$ cm$^2$/s for the lower Queenston Formation

(ix) chloride diffusion coefficient of $1.5 \times 10^{-5}$ cm$^2$/s for the plastic zone and the upper Queenston Formation

(x) rock swelling commences at a reduction in chlorides of 2%

(xi) horizontal rock swelling is equal to 0.6 the vertical rock swelling.

(d) effective stresses, accounting for 100% of the porewater pressure, shall be used in the calculation of confining pressures for use in analyses of rock mass strengths and swelling loads on the liner.

8.4 Tunnel Excavation and Construction

1. The tunnel shall be excavated by means of a TBM starting from the outlet end of the tunnel. The use of drill and blast method of excavation shall be limited to the following areas only:

   (a) intake structure
   
   (b) intake channel
   
   (c) outlet structure
   
   (d) outlet canal
   
   (e) other limited areas subject to the acceptance by the Owner.

2. No drop shafts shall be constructed along the tunnel with the exception of the dewatering shafts and tunnel piezometers.

3. In the Queenston Formation, the initial support must be installed within or immediately behind the shield of the TBM and shall provide full coverage to the rock surface. In the rocks above the Queenston Formation, the initial support must be immediate and full where there is potential for slabbing.

8.5 Tunnel Survey

1. Perform an as-built survey in plan and profile of the completed tunnel and related to the final adjusted tunnel traverse. Profiles shall be taken generally at 50-m intervals and at start and end of horizontal and vertical curves, low points of the tunnel and dewatering shafts and tunnel piezometer locations. Profile measurements shall be taken at $45^\circ$ intervals over the internal perimeter of the tunnel.
2. The final position of the tunnel with respect to the legal limits of the easement must be confirmed by an Ontario Land Surveyor.

3. Reasonable access shall be provided to the Owner to independently audit tunnel TBM guidance systems and tunnel survey.

9. TUNNEL BORING MACHINE

9.1 General

1. Design, manufacture, assemble and test at works, disassemble, deliver to Site, reassemble and test at Site, install and commission a new high-powered, robust, Tunnel Boring Machine (TBM) suitable for safely excavating in the ground conditions as described in the GBR. If the TBM does not have a complete shield, it shall have sufficient shielding and other features necessary to assure safe excavation at all times.

2. Ensure that the electrical components and systems of the TBM, back-up plant and equipment are fully compatible with the site power supply and are suitable for use in a highly corrosive and potentially gassy environment.

3. Use only non-contaminating lubricants.

9.2 Monitoring Equipment

1. Provide remote computer data display and logging systems including real time and historic data capture above ground in the site offices of the Owner.

   (a) Supply a data logging system to comprise a Pentium 4 computer with software, 14-inch color monitor, color printer, modem and CD burner for data.

   (b) Supply communication wiring to provide complete transfer of data of TBM functions.

2. Data transfer and display to include but not be limited to all TBM key functions

   (a) cuttinghead direction, torque, speed and thrust

   (b) gauge cutter pattern

   (c) main bearing lubrication pressure, flow and temperature

   (d) electrical power

   (e) ram pressures

   (f) time, date
(g) stroke
(h) penetration rate
(i) radial pressure on the TBM shield.

9.3 Probing and Proof Drilling Equipment

1. Provide probe drilling equipment suitable for drilling holes for sampling and grouting the rock ahead of the TBM.

2. Provide proof drilling and contact grouting equipment and staging on the TBM backup gantries to enable drilling and grouting through any position around the ring.

9.4 Ventilation Equipment

1. For the purpose of tunnel ventilation equipment design and operation, the tunnel shall be classified as ‘potentially gassy’ in accordance with US Department of Labour OSHA Part 1926. Provide ventilation systems with reversible fans to meet the requirements specified therein.

2. Provide built-in equipment to monitor continuously, and having the capability of giving audible and visual warning of, any hazardous gas concentration above threshold limit values as required by Applicable Laws.

3. Provide build-in equipment to monitor continuously and having the capability of giving audible and visual warning in respect of oxygen levels except that warning devices shall be activated when level falls to threshold limit value as required by Applicable Laws.

4. Routinely maintain monitoring devices in accordance with manufacturers’ recommendations to ensure they are in good working order at all times.

5. Fabricate ventilation ducting from nonflammable material.

9.5 Essential Spares

1. Provide a spare main bearing available for delivery to site within 10 days.

10. TUNNEL WATER-UP PROCEDURES

1. The Contractor shall submit a procedure for tunnel water-up for approval by the Owner, and implement thereafter. Procedure to include testing of sectional service gates, intake and outlet closure gates. Typical tests for gates to include, but are not limited to, checking seal contact and leakage, setting limit switches, setting emergency closing speed, checking hoisting and testing all protection, as appropriate. These tests shall be conducted in dry, wet static and wet flowing conditions, as appropriate.
2. Monitor instrumentation at the instrumented tunnel section during tunnel water-up.

Defined terms used in this Notice have the same meanings given to those terms in the Agreement.

Change to Work

In accordance with Section 5.1(a) of the Agreement, OPG hereby directs the Contractor to make the following changes in the Work:

Expected Change to Contract Price

OPG expects that the changes to the Work set out in this Notice will have the following effect on the Contract Price:

- Contract Price, as set out in the Agreement as of the date of the Agreement $ 
- Total Contract Price, as set out in the Agreement as of the date of the Agreement, as adjusted by all changes in the Contract Price made under all Amendments $ 
- Total expected change to the Contract Price under this Notice $

Expected Change to Contract Schedule

OPG expects that the changes to the Work set out in this Notice will have the following effect on the Contract Schedule:

ONTARIO POWER GENERATION INC.

Appendix 1.1(iii)
Appendix 1.1(iii) - Project Change Notice

PROJECT CHANGE NOTICE

To: Ontario Power Generation Inc.  
Contract: Design/Build Agreement between Ontario Power Generation Inc. and Strabag AG (the “Contractor”) dated □, 2005 (the “Agreement”)

Attn: □  
Fax: □  
Date: □

Defined terms used in this Notice have the same meanings given to those terms in the Agreement.

Change to Work

In accordance with Section 5.2 of the Agreement, the Contractor hereby requests OPG’s consent to make the changes in the Work described in Appendix A hereto (the “Proposed Changes”).

Impact of the Change

Contractor expects that the Proposed Changes will have the impact on the Tunnel Facility Project described in Appendix B hereto.

Expected Change to Contract Price

Contractor expects that the Proposed Changes will have the following effect on the Contract Price, a breakdown of the details of the change to Contract Price are set out in Appendix C hereto:

<table>

Appendix 1.1 (Summary of Work)

1. WORK BY CONTRACTOR

1.1 General

The Contractor shall

1. Perform the Work as required and implied by the Agreement, as shown on the Concept Drawings and in conformance with the Owner’s Mandatory Requirements.

2. Perform the Work in a manner that will assure a service life of 90 years for all the fixed facilities of the Tunnel Facility Project. The Work to be performed by the Contractor includes preparation and submission of analysis and design documentation that clearly demonstrates how the required service life will be achieved and how the Tunnel Facility Project will be constructed in a manner that assures the required service life.

3. Perform the Work in a manner that also ensures compliance with:

   (a) all Applicable Laws, the requirements of the Environmental Assessment (EA) and EA Approval and such other Approvals as the Contractor determines are required for the Project; and

   (b) the requirements of the Community Impact Agreement between OPG and local stakeholders.

1.2 Specific Elements of Work

1. The Work to be performed or provided by the Contractor includes but is not limited to the provision of the following:

   (a) review and consideration of all documentation identified in the Agreement

   (b) identification of all Approvals necessary for the Work, unless specifically excluded in the Agreement, including this Appendix. The Contractor must obtain all such Approvals in a timely manner in order to meet the Contract Schedule.

   (c) final design basis for all elements of the Work including submission of same for review and acceptance by the Owner prior to proceeding with detail design

   (d) geotechnical and other investigations necessary to support the design and construction of the Work

   (e) Specifications for all elements of the Work including submission of same for review and acceptance by the Owner prior to procurement and construction.
Specifications must bear the seal and signature of a Professional Engineer licensed to practice in the Province of Ontario.

(f) engineering analyses and designs for all elements of the Work including submission of same for review and acceptance by the Owner prior to procurement and construction. Analyses and designs must bear the seal and signature of a Professional Engineer licensed to practice in the Province of Ontario.

(g) drawings for all elements of the Work including submission for review and acceptance by the Owner prior to procurement and construction. Drawings must bear the seal and signature of a Professional Engineer licensed to practice in the Province of Ontario.

(h) other Submittals required in the Agreement for review and acceptance by the Owner

(i) revision and resubmission of documents for review and acceptance by the Owner, where such documents had previously been submitted to the Owner and found to be incomplete or unacceptable

(j) submission of the Notice of Project and registration for the Applicable Governmental Authority and execution of responsibilities as the “Constructor”, except with respect to the INCW Part Project

(k) mobilization of all necessary forces, equipment, supplies and other requirements to Site

(l) on-Site trailer accommodation and parking facilities for Owner at the intake and outlet areas of the Site

(m) water and sewage services including necessary connections to municipal services and water meter and metering house

(n) Site access connection to Stanley Avenue at the outlet area and to Portage Road at the intake area

(o) traffic control at entrances and exits to the Site areas including traffic control devices and traffic control personnel and paid-duty police as necessary

(p) site security, public safety and emergency response in accordance with the minimum requirements set out in Appendix 2.4(g)(3)

(q) provision of all temporary construction facilities and services to enable and facilitate the performance of the Work

(r) environmental protection measures required by the Agreement and required by Applicable Laws
(s) disposal of Hazardous Materials to an off-Site location provided by the Contractor
(t) construction power including connections to appropriate power supplies
(u) emergency power supply at the intake and outlet areas to provide back-up power to all safety systems and other critical Site functions
(v) unhindered access for Owner to the Site, fabrication, manufacturing and test locations associated with or related to the Work
(w) temporary facilities (including temporary structures) necessary and required to facilitate performance of the Work. Submit details, designs and drawings of all temporary works to Owner for review and acceptance, prior to procurement or installation. Submitted designs and Drawings of temporary works must bear the seal and signature of a Professional Engineer licensed to practice in the Province of Ontario. Remove and dispose off-site all temporary works when no longer required for the performance of the Work
(x) in-river approach channel at the intake area
(y) in-river approach wall along the river bank at the intake area
(z) a temporary groyne upstream of the INCW structure to enhance ice flow in the intake channel during construction. Remove and dispose of groyne prior to removal of intake area cofferdam
(aa) modification and extension of the INCW structure
(bb) demolition of the existing in-river accelerating wall at the tunnel intake area and off-site disposal of same at location(s) provided by the Contractor and acceptable to the Owner
(cc) disposal of excavated and other surplus materials from the tunnel intake area at an off-Site location(s) provided by the Contractor and acceptable to the Owner
(dd) in-river accelerating wall at the intake area, including installation of navigation strobe light on new wall with associated cabling and connection to power supply at INCW and installation of fall arrest on new wall
(ee) supply, installation and calibration of intake gauge, acceptable to the Owner
(ff) supply, installation and calibration of intake gauge, acceptable to the Owner
(gg) tunnel intake structure and associated work to interface with and connect to existing structures and facilities
(hh) tunnel intake sectional gate, including removable guide extension to river surface and associated platforms to provide safe installation and removal, and associated requirements including removal of sectional gate after tunnel commissioning and transportation and unloading of same at a facility to be designated by the Owner within 25 km of the Site

(ii) tunnel outlet structures and related facilities

(jj) outlet canal between the tunnel and the existing canal system at the outlet area

(kk) demolition and disposal to off-Site location(s) of the existing dewatering structure in the PGS canal. This element of Work shall be undertaken only at the sole option and direction of the Owner.

(ll) new tunnel boring machine (TBM) and required backup and support equipment to construct the diversion tunnel. Contractor to dismantle the TBM at completion of tunnelling and remove from the Site

(mm) diversion tunnel facility including tunnel driving, water inflow management, probe drilling, ground consolidation and support, installation of tunnel lining, installation of tunnel grouting, tunnel cleanup and tunnel finishing

(nn) material handling and management systems to transport, place, compact and manage excavated material from the outlet area and the tunnel drive to the on-Site Owner-designated disposal site

(oo) leachate collection and handling systems, leachate treatment and disposal systems at excavated material storage areas on Site as required by the Agreement, Applicable Laws and Approvals

(pp) instrumentation necessary for the performance of the Work, including instrument reading, data reduction and provision of data to Owner in a timely manner, at least monthly, and at significant construction events

(qq) instrumented tunnel section

(rr) installation of four tunnel piezometers into the tunnel crown to an average depth of 180 m below grade

(ss) establishment and maintenance of necessary QC/QA for performance of the Work and submission of copies of all QC/QA and related reports to the Owner in a timely manner

(tt) tunnel dewatering shafts and associated civil infrastructure

(uu) tunnel outlet gate and associated hoisting, electrical and control requirements including interconnectors to permanent power supply
(vv) rework necessary to achieve compliance with the Agreement

(ww) maintenance of temporary facilities, services and environmental protection until the later of the Final Completion Date and any date established in any Approvals or Applicable Laws

(xx) water-up and commissioning of the diversion tunnel and associated facilities. Allow for detailed inspection of tunnel by the Owner prior to water-up

(yy) sounding survey in the PGS canal both before and after connection of the outlet canal to the PGS canal, to determine changes in the side and bottom profile of the canal as a result of the Work

(zz) removal of rock and other debris from the PGS canal, deposited as a result of performance of the Work

(aaa) Flow Verification Test

(bbb) restoration of all areas of the Site

(ccc) as-built drawings

(ddd) affidavit(s) of compliance signed by Engineer(s) of Record

(eee) operations and maintenance manuals and training of OPG personnel

(fff) demobilization and removal of all temporary facilities and services from the site

(ggg) any requirements for communications with INCW personnel and other persons affected by Contractor activities

(hhh) support and assistance to Owner with respect to reporting requirements required for compliance with Project Approvals

(iii) support and assistance to Owner with respect to implementation of the Community Impact Agreement

(jjj) obtain necessary exemptions for navigation in the Niagara River

(kkk) administration of the Jagger Hims Limited groundwater monitoring program.

1.3 Environmental Approvals

1. The Environmental Assessment Approval for the Project includes a number of Conditions that must be met during the planning, design and construction of the Tunnel Facility Project. Table 1.1A, in this Appendix, indicates responsibility for developing documentation and obtaining respective Approvals. Table 1.1A is not intended to detract from the Contractor’s obligation to comply with the
Environmental Assessment and the EA Approval, and all procedures, programs, plans and clearances thereunder. For purposes of interpreting the “Summary of Condition” column in Table 1.1A, the EA Approval should be reviewed in its entirety.

2. The abbreviations in Table 1.1A have the following meanings:

(a) $P =$ Primary responsibility for preparing and submitting required documentation, obtaining and implementing Approvals, if applicable

(b) $P1 =$ Primary responsibility for preparing and submitting initial documentation, and reviewing and submitting final documentation and obtaining Approvals

(c) $P2 =$ Primary responsibility for finalizing documentation and submitting to OPG for review, and supporting obtainment of Approvals

(d) $S =$ Support to the Party with primary responsibility for developing documentation and obtaining Approvals including collecting and providing data and information, and attending meetings.

3. Approvals, recommendations and exemptions under the following treaties and acts have been obtained.

(a) International Niagara Diversion Treaty

(b) Navigable Waters Protection Act

(c) Department of Fisheries and Oceans Authorization 5250-43

   (i) Authorization for Destruction of Fish by Means other than Fishing (including Amendment, Amendment #2 and Amendment #3); and

   (ii) Authorization for Works or Undertakings Affecting Fish Habitat (including Amendment, Amendment #2 and Amendment #3).

4. Other environmental Approvals and responsibility for obtaining such Approvals include those shown in Table 1.1B, where $P$ and $S$ have the meaning given in Section 1.3(2) in this Appendix.

5. The Contractor shall abide by the conditions and requirements included in all of the above Approvals, recommendations and exemptions.

2. WORK BY OTHERS

1. The following work is to be undertaken by others and is not included in the Work to be performed by the Contractor:

(a) subject to Sections 2.15(b) and 2.15(k) of the Agreement, obtaining rights of way
(b) installation of groundwater monitoring wells necessary to achieve compliance with the EA Approval

(c) temporary recreational trail in the vicinity of the intake area

(d) access barriers and parking for operators at INCW

(e) installation of survey control monuments at the intake and outlet areas

(f) OPG manages ice flushing at the INCW. OPG will make its best efforts to ensure that ice is continually flushed past the construction area.

(g) OPG manages Grass Island Pool (GIP) water levels and outflow to meet 1950 Niagara Treaty requirements

(h) pre-construction and post-construction condition surveys of existing infrastructure for review and acceptance by the Contractor and other interested parties

(i) control and operation of the Sir Adam Beck Generating Complex during performance of the Work

(j) construction at the outlet area access road to the right-of-way at Stanley Avenue and Portage Road at the intake area

(k) provision of sewer and water interconnection point at the east side of Stanley Avenue right-of-way at the outlet area

(l) installation of first order horizontal and vertical control monuments at the outlet and intake areas for tunnel set out and survey control.

3. CONSTRAINTS

1. Performance of the Work will be constrained by a number of requirements that include, but are not limited to, the following:

   (a) the drill and blast method of tunnel construction will not be permitted

   (b) access shafts, drop shafts and ventilation shafts will not be permitted along the tunnel alignment

   (c) flow disruption in the power canals will not be permitted except as follows:

      (i) flow may be interrupted in the PGS canal for no more than 6 hours in duration, in any 48-hour period, for Work associated with

         - connection of the outlet canal to the PGS canal
- for Work associated with demolition and disposal to off-site location(s) of the existing dewatering structure in the PGS canal should such Work be directed by the Owner

(ii) Contractor to provide a tentative schedule of any required interruption of flow in the PGS at least 3 months prior to the required interruption

(iii) Contractor’s schedule will show, and Contractor’s operations will support, a maximum overlap of Work associated with connection of the outlet canal to the PGS canal and Work associated with demolition and disposal to off-site location(s) of the existing dewatering structure in the PGS canal such that the total number of 6-h closures required is at a minimum

(iv) Contractor to provide at least 5 calendar days Notice if it requires interruption of flow in the PGS

(v) in all cases, Owner determines at its sole discretion the specific date and time for allowable interruption of flow in the PGS canal

(d) The more stringent of the following requirements will apply:

(i) On-Site and off-Site activities governed by the Niagara Falls Noise Control By-Law 2004-105 and relating to the performance of the Work shall comply with such By-Law except for TBM tunneling Work and any other exemptions that may be obtained by the Contractor.

(ii) On-Site and off-Site activities governed by MOE Publication NPC 205 and relating to the performance of the Work shall comply with such publication at sensitive noise receptors unless specific exceptions have been approved by MOE.

(iii) Truck traffic to and from the Site at the intake area shall not take place on Sundays unless noise at sensitive receptors are mitigated to OPG’s and MOE’s satisfaction.

(e) load limits on INCW deck structure - GVW of 90 tonnes for triple axle vehicle, GVW of 36 tonnes for double axle truck

(f) tourist movement, both pedestrians and vehicular

(g) Marine Operation at the INCW

- Tourist Season Flow (TSF) is defined as

   (i) April 1 through September 14, inclusive, and during the hours of 08:00 to 22:00, inclusive
(ii) September 15 through October 31, inclusive, and during the hours of 08:00 to 20:00, inclusive

(iii) all other hours during these periods are defined as the nighttime hours.

- Reference Drawing 6-B-214 defines restrictions on ice breaking operation near the INCW structure. These restrictions shall be followed for all marine operations in the river.

- During the TSF, fourteen of the existing eighteen gates must be available to pass the required scenic flows to the Niagara Falls. In the nighttime hours, all bays are normally closed and unrestricted marine operations can take place subject to obtaining approval for nighttime construction activity in this area. However, abnormal streamflow or power entity diversion restrictions may require operation of INCW gates during the TSF nighttime hours.

- The Contractor shall be aware that conditions on the river and the gates in the INCW can change at any time. The Contractor shall interface with OPG regarding operation at the INCW.

- During the period from December 15 through April 30, inclusive, or as otherwise indicated by OPG, no marine based operations or other in-water activities shall take place that affect ice management as determined by OPG.

- Installation of the new Ice Accelerating Wall and removal of the existing Ice Accelerating Wall shall be completed before construction of the cofferdam upstream from INCW Bay 1. A minimum of three bays must be available within the ice channel for ice management at all times.

(h) INCW Part Project Area

The gates at the INCW are required to be under the control of OPG at all times during execution of the Tunnel Facility Project. In addition, OPG requires regular access along the INCW structure to service and maintain the gates. A comparatively small portion of the Tunnel Facility Project requires the Contractor to perform certain in-water elements of Work in an area near and on the INCW structure as shown on Drawing NAW130-D0E-80000-0015 in Appendix 1.1(h) and defined as the “INCW Part Project Area”. During the time period when this portion of the Work is performed, OPG will assume the role of “constructor” (as that term is used under the Occupational Health and Safety Act (Ontario)) for the INCW Part Project Area only.

OPG shall only be the constructor in this limited area, and only during the specific times to be agreed upon in advance in writing by OPG and the Contractor, for the performance of the relevant portion of the Work by the Contractor, including
• construction of the new ice accelerating wall and removal of the existing ice accelerating wall
• underwater excavation (if any) for the intake approach channel
• construction of the cofferdam
• placement and or removal of the sectional service gates
• dismantling and removal of the cofferdam.

The Contractor shall only have access to the INCW Part Project Area at the agreed times. The Contractor shall take specific precautions to ensure that it does not access the INCW Part Project Area at any other time.

(i) Regional Roadworks

On behalf of OPG, the Regional Municipality of Niagara will be reconstructing Stanley Avenue (Regional Road 102) from Whirlpool Road to Niagara Townline Road with intersection improvements at Portage Road, the outlet construction site access road entrance, and Thorold Stone Road commencing approximately August 2005. Intersection improvements will also be undertaken at the intake construction site access road entrance on Portage Road south of Upper Rapids Boulevard.

4. SPECIFIC SITE CONDITIONS

4.1 Survey Datum

1. UTM Universal Transverse Mercator
2. NAD North American Datum
3. IGLD International Great Lakes Datum
4. USLS United States Lake Survey

5. Horizontal control for the survey in the project area is a UTM projection based on the NAD83 datum. A second order horizontal control network is represented by several monuments throughout the Site. The Owner grid previously used at the Site shall only be used for reference so that existing drawings can be oriented to the current Work.

6. The coordinates of the tunnel right-of-way defined on Drawing NAW130-D0E-29230-0015 are based on second and third order horizontal control.

7. Vertical control is based on Geodetic Surveys of Canada (GSC), Fifth Edition (1983), vertical datum. Where NAD83 is referred to as a vertical datum, it is meant to be GSC 1983 and are, therefore, considered equivalent within this agreement. However,
the stated elevations on vertical control monuments in the project area vary according to the agency which has previously surveyed the area. To establish a single datum, existing elevation data from the IGLD have been converted to NAD83 by means of the elevation relationships shown in the following table. IGLD55 is an imperial datum while IGLD85 is a metric datum. The conversion between IGLD55 and IGLD85 is geographically dependent with specific conversion defined below for the Material Dock gauge and the cross-over gauge locations.

<table>
<thead>
<tr>
<th>To Get</th>

4.3 OPG’s Site Office Facilities

1. OPG’s offices shall be provided in trailers, GE Capital or equal, and located as agreed by OPG.
2. Provide and maintain an office complex for OPG at the main site area at the outlet with a minimum area of 300 m², with floors able to withstand 4.8 kPa live loads, and covered with resilient flooring. The office shall contain a meeting room, storage room, gallery area, reception and secretarial area, lockable air conditioned computer room, washrooms and offices for OPG’s staff. The layout of the office shall be determined by OPG.

3. Provide and maintain an office trailer for OPG at the intake Site with a minimum of 60 m². The office shall contain a meeting room, gallery area, washroom and offices for OPG’s staff.

4. Provide lighting to uniformly deliver not less than 100 footcandles at desk height in all areas except the restrooms. Adequately light and ventilate the change room, complying with code requirements.

5. Locate exterior lighting over the entrance doors. Provide grounded duplex electrical receptacles at approximately 3-m spacings for interior walls, with at least one in each wall except in the restrooms.

6. Provide automatic heating and air conditioning equipment capable of maintaining an ambient office temperature between 20°C and 25°C.

7. Provide drinking water chilled by an electrically operated drinking fountain.

8. Provide separate staff change rooms, with mine safety personnel clothing and equipment storage, for male and female staff. The male washroom to include two urinals, two flush toilets, two wash basins and two showers. The female washroom to include one flush toilet, one wash basin and one shower. Both washrooms to be provided with a mirror, grounded duplex electrical receptacle, soap holder, toilet paper holder, paper towel dispenser, waste basket and related supplies.

9. Provide a hot water heater of not less than 400 L storage capacity.

10. Provide doors and locks for exterior doors to each office and interconnecting doors between offices where applicable depending on the floor plan agreed to by the Engineer. Doors between the central office and the washrooms shall have a privacy lock. Exterior doors shall have cylinder keyed alike, and sixteen keys shall be furnished for each lock.

11. Provide a burglar alarm motion detection systems with a central control box and audible alarm to secure the entire facility. Provide burglar proof bars in all windows. Provide a smoke detector system and alarms.

12. Provide a telephone system consisting of six external lines plus intercom and twelve extensions in addition to a dedicated line for a fax machine. The telephone system shall include a speaker phone with dedicated line, touch tone dialing with hold button feature, plus one phone for the fax machine. OPG will determine the distribution of equipment and telephone service in the office. The Contractor shall pay monthly
charges for the telephone system but long distance calls are for OPG’s account. Provide high speed internet connection.

13. Provide office furnishings of the type and quantity listed below.

DELEGATION OF AUTHORITY
(or change in delegation of authority)

To: Ontario Power Generation Inc. (“OPG”)

Contract: Design/Build Agreement dated •, 2005 between Strabag AG (the “Contractor”) and OPG (the “Agreement”)

Delegation No.: •
Date: •

Defined terms used in this Notice have the same meanings given to those terms in the Agreement. In accordance with Section 2.2(b) of the Agreement, the Contractor hereby delegates authority to the individuals named below for the subject matters and subject to the limitations set out in this Notice. These delegations will continue in full force until revoked by the Contractor in another delegation of authority Notice.

Title: ____________________________
Appendix 2.4(c)
Appendix 2.4(d)
Appendix 2.4(d)- Preliminary Project Specific Site Safety, Security, Public Safety and Emergency Response Plan

[See attached]
June 23, 2005

Mr. Harry Charalambu
Hatch Mott MacDonald
Consulting Engineers
2800 Speakman Drive
Mississauga, Ontario
L5K 2R7

Dear Mr. Charalambu:

Re: Niagara Tunnel Facility Project – Design/Build Contract

Please find enclosed the Project Site Specific Safety Plan for the OPG Niagara Tunnel Project as requested during the June 16, 2005 meeting in Mississauga detailing additional submissions requested under 1.11 SAFETY originally noted in the May 20, 2005 “Strabag Question and Answer” document. In addition, a copy of Dufferin Construction Company’s Health and Safety Program has been included in conjunction with our Subcontractor, McNally Construction Inc. handling all marine work.

We have attempted to capture an overview of the project’s health and safety requirements relating to the project’s construction activities. Specific references to the draft Emergency Response/Rescue Plan have been highlighted in the document detailing our intent to implement a comprehensive program which will mitigate and manage any potential emergency situation in the tunnel or those involving surface work. The construction team will be utilizing the expertise and existing tunneling emergency procedures brought to us by the technical experts from Strabag. The Health and Safety team will ensure the standards and processes introduced by Strabag exceed the minimum requirements of Ontario’s Occupational Health and Safety Act and the Regulations for Construction Projects.

The Health and Safety Team will incorporate existing best practices from all members of the Design/Build Team’s Company policies and develop site specific safe working procedures for the Niagara Tunnel Project. These will include noted concerns regarding the Public Safety and Site Security Plan. The outline details methodology to ensure the existing high level of security and public protection currently in place along the Niagara Parkway remain with the greatest standard of care.

The keys to success of any project require proactive health and safety measures are developed and implemented prior to the start-up of any construction activity. A critical component of a world class safety program will include a formal health and safety orientation training program for all workers as they begin their tasks on the site. The
Strabag and Dufferin Team will implement such a program and follow-up with on-going hazard awareness training throughout the duration of the project. Training programs will be wide ranging and provide added protection to workers performing the various activities relating to the project. In addition, Supervisory training will be in place to ensure all incidents are reported and actively investigated by competent persons to prevent recurrence. Our staff has received extensive training in Practical Loss Control techniques and has demonstrated the effectiveness of job hazard analysis practices preventing unnecessary harm to people, process, property and the environment.

Our firm is implementing an Occupational Health and Safety system parallel to the ISO 18000 guidelines dealing with people related, process related and management related safety objectives. The OHS Management system program is well underway at St. Lawrence Cement and the Niagara Tunnel Project will provide an excellent opportunity to measure the added value a structured approach to OHS will offer. We anticipate a successful project completion and our goal is to exceed the expectations of OPG should our proposal be accepted.

We look forward to continued discussion and value the input OPG will offer throughout the selection process. Should you require further information or clarification on any safety related matter, please contact the undersigned at any time.

Sincerely,

Dufferin Construction Company
A business unit of St. Lawrence Cement Inc. on behalf of partners at Strabag:

Jim LaFontaine  B. Tech., CRSP
Health, Safety and Environmental Manager

</table>
| Fire Protection          | All Construction Phases of the Intake/Outlet and Tunnel                                    | 1. Fire Protection Plan will incorporate existing Strabag fire prevention policies and utilize the fire brigade system used on projects currently underway by Strabag personnel.  
2. Fire Plan will utilize designated fire suppression systems in strict accordance of the Construction Regulations Sections 248-259  
3. Workers inside the tunnel will receive site specific training in fire suppression systems and there will be adequate members of the fire brigade team in place for each shift.  
4. Ensure Fire Extinguishers are located at various locations and installed on various equipment throughout the project  
5. Ensure fire extinguishers are located adjacent to hot work operations  
6. Apply a hot work permit system and include a “fire-watch” when performing hot work or when other conditions warrant.  
7. Prevent access underneath hot-work activity areas by placing an appropriate barrier and warning signs advising of “Danger Do Not Enter – Hot Work Overhead”  
8. Inspect fire extinguishers at least monthly to ensure they are fully charged  
9. Supply necessary training in the use of fire extinguishers and area aware of hot-work practices. Request subcontractors to provide training records of all staff regarding use of fire extinguishing equipment.  
10. Notify Niagara Regional Police/Fire and Rescue of the Fire Protection plan. Conduct mock rescue with the emergency team to simulate emergency situation. Ensure rescue team is brought to the site and provides comments/concerns of potential issues | Strabag Senior Project Manager in conjunction with H&S Officer                                                                   |
| Emergency Response/Rescue Plan | Tunnel Evacuation, Medical Emergency or other situation                                      | 1. Strabag will institute tunnel entry procedures to include a tagging system identifying every worker who enters the tunnel. In the unlikely event an evacuation of the tunnel is required, a detailed head count will ensure all workers have been accounted for at the evacuation station.  
2. Workers will be transported into the tunnel via a shuttle type system which will also allow for extraction of injured or those who suffer any type of medical emergency. First-aid kits will be stationed at various intervals throughout the length of the tunnel.  
3. Competent Supervisors in the tunnel will have been well trained in                                                                 | Strabag and H&S Officer to develop/finalize in detail upon award.  
Senior Project Superintendent will ensure the Plan is communicated and  |

<tr>
<td>2. Ventilation of tunnel</td>
<td></td>
</tr>
</tbody>
</table>

1. Communicate WHMIS Procedure to employees during orientation program
2. Obtain a copy of subcontractor's WHMIS policy and all MSDS
3. Ensure all hazardous material containers supplier or workplace

Program to be detailed after award of contract by H&S Officer
### Chemical and Occupational Health Considerations (cont’d)

4. Review hazardous chemical data sheets prior to use
5. Ensure training has been provided to all workers relating to hazardous material exposure control:
   a. Where required due to exposure to hazardous chemical, implement hygiene practices, eye wash station, etc.
   b. Noise control and protection requirements;
   c. Welding flash protection requirements.
6. Review procedures to prevent exposure to welding flash, cutting related exposure
7. Notify personnel of hazard control practices
8. Conduct continuous air monitoring to ensure there is no hazardous atmosphere inside the tunnel and cofferdams during construction activities.
9. Develop and implement site specific air monitoring program
10. Develop and implement site specific confined space entry program and procedures
11. Implement engineering controls to ensure adequate air supply using Strabag’s proposed ventilation system purging fresh air into tunnel on a continuous basis
12. Maintenance of the fans, blowers, filters as per the manufacturer’s recommended guidelines
13. Storage of chemicals, propane, all other compressed gases to be in strict compliance with Trans of Dang Goods, Energy Act, TSSA or other related legislation relating to hazardous substances

### Hazard Condition | Associated Process or Phase | Control Procedure | Action
---|---|---|---
Other Occupational Health Considerations | Tunnel Air Quality 1. Respiratory protection to protect personnel who may be exposed to welding fumes, related cutting fumes, silica dust, diesel fumes 2. Protection of public from generated fumes; 3. Hearing protection when noise exposure may exceed 90 dBA (TWAEV) 4. Protection of workers and public form welding flash; | Strabag/Dufferin and subcontractor to confirm the following:
1. Processes and chemical substance will not create a hazardous atmosphere in or surrounding region.
2. Internal combustion powered equipment is not used within the enclosed tunnel unless adequate supplemental ventilation is provided;
3. Provide wash-up facilities and encourage their use to remove residual dust, welding & cutting fumes that has contacted skin which may pose a hazard
4. Ensure employers provide all exposed workers:
   a. NIOSH approved respiratory protection when workers may be exposed to hazardous welding fumes, lead based paint dust or... | Strabag Project Management Team and Dufferin Project Superintendent in conjunction with H&S Officer/Industrial Hygienist

Strabag to implement air quality monitoring/ventilation and medical monitoring program in line with OH&SA Regulations and Company policy
### Other Occupational Health Considerations (cont’d)

- Fumes, other paint dust or fumes;
- Hearing protection during noise producing operations;
- Appropriate safety eye wear;
- Ensure training has been provided to all workers relating to hazardous material exposure control:
  - Where required due to exposure to hazardous chemical, implement hygiene practices, eye wash station, etc.
  - Noise control and protection requirements;
- Welding flash protection provisions for the public;
- Notify all personnel of hazard control practices via weekly tailgate training; hazard alert and safety bulletins.

### Hazard Condition | Associated Process or Phase | Control Procedure | Action
--- | --- | --- | ---
**Occupational Health Considerations**  
Asbestos Containing Material  
Demolition Phase  
Asbestos containing material may be present in the form of asbestos containing concrete electrical conduit. Conduit may be located in structures and cable trays located in concrete structures.  
**NOTE:** owner to advise if asbestos on the project  
Request Asbestos Abatement subcontractor to confirm the following provisions:  
1. Develop a plan to support the provisions of the designated Substance Regulation;  
2. If a Type 3 operation occurs, notify the Ministry of Labour orally and in writing, prior to the commencement of the operation;  
3. Ensure workers are provided with sufficient respiratory protection. Respiratory protection shall conform to the provisions set out in Sec. 10 of the Designated Substance Regulation;  
4. Measures and procedures for Type 1 operations shall conform to the provisions set out in Sec. 11 of the Designated Substance Regulation;  
5. Measures and procedures for Type 2 and Type 3 operations shall conform to the provisions set out in Sec. 12 of the Designated Substance Regulation;  
6. Measures and procedures for Type 2 operations shall additionally conform to the provisions set out in Sec. 13 of the Designated Substance Regulation;  
7. Measures and procedures for Type 3 operations shall additionally conform to the provisions set out in Sec. 14 of the Designated Substance Regulation;  
8. Train all workers who may be exposed to the hazards of asbestos containing material. Training shall consist of the provisions set out in Sec. 15 of the Designated Substance Regulation;  
9. Complete Form 1. Asbestos Work Report for each worker that performs Type 2 or Type 3 operations.  
To be determined

2. Placement of cofferdam structure using barges  
3. Certification of all marine equipment, marine surveys, emergency plan compliance  
4. All workers tied off to anchor system on barge using CSA approved fall arrest systems  | McNally Health and Safety submissions |
| Public and Worker Protection During Hoisting Phase | Hoisting and Rigging                  | 1. All operators of hoisting equipment to be licensed by the MTCU, and members of Local 793 Operating Engineers  
2. Certificate of Non destructive testing for all hoisting equipment within the last 12 month period.  
3. Inspection of crane by competent worker  
4. Inspection records for hoisting and rigging equipment – tagged; documentation required  
5. Safe hoisting procedures  | Procedures for high risk lifts, pumping concrete to be established by Site Superintendent |
| Material Transfer                      |                                       | 1. Use of conveyer system over PGS Canal to transport muck from TBM at outlet structure  
2. Erection of conveyors as per engineered drawings  
3. All guarding of conveyer systems in accordance with CSA requirements  
4. Training of workers regarding machine guarding awareness/lock-out tag-out  
5. Inspection of conveyer system as per guidelines; maintenance of belts, return idlers, tail and head pulleys  | Strabag Project Management Team to develop engineered plan upon award of contract |
### Engineered Structural Support Systems

**Cofferdam:**
- Intake Structure Construction

1. Design structural support and inspect to ensure cofferdam system is installed consistent with the design
2. Inspect regularly to ensure maintenance of hazard controls
3. Design formwork and falsework to support loads
4. Ensure design work is stamped by a P. Eng
5. Inspect form/falsework by P. Eng or designated competent person to ensure that form and falsework is erected in accordance with the design and will be capable of supporting all loads to be applied
6. Inspect prior to placement of concrete
7. Monitor during concrete placement to identify changes of conditions that may affect form falsework integrity.

**McNally to manage marine work – submit approved methodology and engineered shop drawings for cofferdam**

### Engineered Support Systems (cont’d)

**Engineered Fall Protection**
- All Phases:
  - Horizontal lifelines

1. If applicable, design horizontal lifeline systems and inspect to ensure system is installed consistent with the design
2. Inspect regularly to ensure maintenance of hazard controls
3. Install adequate access and egress from the cofferdam

**Project Superintendent of Dufferin to ensure all Fall Protection measures in place where workers are exposed to fall hazard > 2.4m.**

Niagara Tunnel Project

Health, Safety & Environmental Efforts

We are pleased to inform you that Austria ranks in a top position of the European Member States (among the top 5 countries) concerning the enforcement of EU directives and guidelines for statutory expressed Industrial Safety Standards.

The Austrian legislation obliges every Austrian company to comply with the EU directives and guidelines for Industrial Safety. Any non-compliance is punished with severe civil penalties and fines.

The Safety Training of new hired site personnel before beginning of work is part of the statutory Safety Standard in Austria as well as the periodic training and the instruction on the building machinery and construction equipment.

Every company has to provide a sufficient number of safety personnel who have to attend periodic safety trainings and have to control and enforce the Industrial Safety Standards on each jobsite.

STRABAG Group is the only private company in Austria authorized for training and certification of Safety Personnel in accordance to the EU directives (please refer to attached administrative decision of Austrian Ministry for Work, Health and Social Concerns – Job Safety Agency). This was one of the reasons for nominating our group for the State Honour for Work Safety 2003.

We also like to inform you that STRABAG is certified in accordance to ISO 14001 for the implementation and maintenance of an Environmental Management System as well as to SCC®- Safety Certificate Contractors for application and further development of an effective Safety Management System complying with the requirements of the SCC Standard.
Administrative Decision
Training of Safety Personnel
Bundesministerium
für Arbeit, Gesundheit und Soziales
Zentral-Arbeitsinspektorat

Wien, 1. April 1999

Betreff: Sicherheitsvertrauenspersonen und Präventivdienste;
Anerkennung der Fachausbildung von Sicherheitsfachkräften gemäß § 6 SFK-VO.

Bescheid

Für diesen Bescheid ist gemäß Tarifpost 1 der Bundes-Verwaltungsabgabenverordnung 1983, BGBl.Nr. 24, eine Verwaltungsabgabe von 50.– (Schilling sechzig) zu entrichten.

Begründung:

Das Bundesministerium für Arbeit, Gesundheit und Soziales, Zentral-Arbeitsinspektorat, hat gemäß § 6 Abs. 2 SFK-VO den gesetzlichen Interessenvertretungen der Arbeitgeber/innen und Arbeitnehmer/innen und dem Bundesministerium für Wissenschaft und Verkehr im Verfahren Gelegenheit zur Stellungnahme gegeben.

Seitens der Bundesarbeitskammer erfolgten keine Einwände gegen die Anerkennung der Fachausbildung gemäß § 8 SFK-VO. Das Bundesministerium für Wissenschaft und Verkehr, Verkehrs-Arbeitsinspektorat, verlangte zusätzliche verkehrsspezifische Lehreninhalte. Die Wirtschaftskammer Österreich gab im Rahmen des Anhörungsverfahrens keine Stellungnahme ab.

Abteilung: VU3, Auskunft Gerda Ecker, OW: 6323
A-1020 Wien, Praterstraße 31, Tel.: (01) 71100 Fax: (01) 71100 2196, DVR: 0017001

Laut vorgelegtem und durch das Schreiben vom 19. Februar 1999, ergänzt durch das Schreiben vom 25. März 1999, nach dem Paratleugab für kürzerten Ausbildungsplan, umfaßt die Fachausbildung der BRVZ Bau-, Rechen- und Verwaltungs- zentrum Gesellschaft m.b.H. 298 Unterrichtseinheiten, welche auf zehn Themengebiete i.S.d. § 1 Abs. 2 2 1 bis 10 und Abs. 3 SFK-VÖ wie folgt verteilt sind:

1. Einführung und Grundlagen (mindestens 8 Unterrichtseinheiten):
   8 Unterrichtseinheiten
2. Rechtsgrundlagen und Normen (mindestens 32 Unterrichtseinheiten):
   35 Unterrichtseinheiten
   34 Unterrichtseinheiten
4. Sicherheit von Arbeitssystemen mit Anwendungsfällen
   (mindestens 50 Unterrichtseinheiten):
   81 Unterrichtseinheiten
5. Ergonomie, Grundlagen und Anwendung (mindestens 24 Unterrichtseinheiten):
   26 Unterrichtseinheiten
6. Schadstoffe, Grundlagen und Anwendung (mindestens 19 Unterrichtseinheiten):
   24 Unterrichtseinheiten
7. Ermittlung und Beurteilung von Gefahren, Festlegung von Maßnahmen
   (mindestens 10 Unterrichtseinheiten):
   24 Unterrichtseinheiten
8. Kosten-Nutzen-Analyse (mindestens 10 Unterrichtseinheiten):
   10 Unterrichtseinheiten
9. Psychologische und betriebssoziologische Grundlagen des Arbeitnehmer-
   erreichenschutzes (mindestens 27 Unterrichtseinheiten):
   28 Unterrichtseinheiten
10. Schnittstellen mit verwandten Sachgebieten, insbesondere dem Verkehrswesen
    (mindestens 7 Unterrichtseinheiten):
    28 Unterrichtseinheiten.

Im Sinne der Bestimmungen des § 1 Abs. 4 SFK-VO über die blockweise Durchfüh-
run des Fachausbildungs, wird der Lehrgang in vier Blöcken zu je zwei Ausbildung-
wochen, durchgeführt. Ein Abschluß des Ausbildungslehrganges ist nach erfolgrei-
cher Ablegung der Abschlußprüfung nach Beendigung des letzten Blocks innerhalb
einer zweijährigen Frist des § 1 Abs. 4 SFK-VO gewährleistet.

Die Ausbildungsleitung gemäß § 4 SFK-VO erfolgt durch Ing. Johannes Pestal, wel-
cher über eine Ausbildung als Sicherheitsfachkraft und als ehemaliger Arbeitsein-
spektor und Vortragender bei diversen Schulungen und Unterweisungen im Bereich
Arbeitnehmer schutz über langjährige einschlägige Berufs- und Organisationserfah-
nung verfügt.

Als Vortragende sind vorgesehen:
Vertreter/innen des Zentral-Arbeitsinspektorats, der Arbeitsinspektion, Vertreter der
AUVA der Verkehr-Arbeitsinspektion, Arbeitsmediziner und Sicherheitsfachkräfte

Die fachliche Qualifikation der vorgesehenen Lehrkräfte i.S.d. § 5 Z 2 SFK-VO ergibt
sich aus deren Ausbildung und beruflichen Tätigkeit insbesondere im Bereich des
Arbeitnehmerschutzes.

Die Durchführung der Fachausbildung soll in den Räumlichkeiten der Bildungsaka-
demie der Bau Holding AG, 9800 Spittal/Drau, Ortenburgerstraße 27, erfolgen, so
daß die entsprechende Ausstattung und die Lehrmittel i.S.d. § 5 Z 3 in den Sem-
narräumen vorhanden sind.

Die Abschußprüfung gemäß § 3 Abs. 2 bis 5 SFK-VO wird in Form einer schriftli-
chen und mündlichen Prüfung durchgeführt.

Die auf Grund der §§ 74 und 90 Abs. 1 Z 1 des Bundesgesetzes über Sicherheit und
Gesundheitsschutz bei der Arbeit (Arbeitnehmerlernenschutzgesetz - ASchG), BGBl.
Nr. 450/1994, ergangene Verordnung des Bundesministers für Arbeit und Soziales
über die Fachausbildung der Sicherheitsfachkräfte (SFK-VO), BGBl.Nr. 277/1995,
sieht eine Anerkennung der Fachausbildung mit Bescheid gemäß § 6 Abs. 1 SFK-
VO, vor, wenn der laut Antrag gemäß § 5 SFK-VO vorgelegte Ausbildungsplan den
Voraussetzungen des § 1 SFK-VO über Inhalt und Umfang der Fachausbildung ent-
spricht und gewährleistet ist, daß die personellen und sachlichen Voraussetzungen
der Ausbildungseinrichtung zur Erreichung des Ausbildungsziels gegeben sind.
Gemäß § 1 Abs. 4 SFK-VO kann die Fachausbildung blockweise durchgeführt werden, wobei die einzelnen Ausbildungsabschnitte mindestens zwei Wochen betragen müssen und die Ausbildungseinrichtung zu gewährleisten hat, daß die Fachausbildung bei normaler Ausbildungsgang innerhalb von zwei Jahren abgeschlossen werden kann.

Die Verteilung der Differenz von 68 Unterrichtseinheiten gemäß § 1 Abs. 3 SFK-VO, welche sich aus der Gesamtzahl von mindestens 288 Unterrichtseinheiten und den in § 1 Abs. 2 Z 1 bis 10 SFK-VO verbindlich nach Fachgebieten vorgeschriebenen 220 Unterrichtseinheiten ergibt, auf die Ausbildungsgegenstände der SFK-VO bleibt den einzelnen Ausbildungseinrichtungen nach individuellen inhaltlichen und didaktischen Gesichtspunkten im Rahmen des von der SFK-VO eingeräumten Spielraumes vorbehalten.

Gemäß § 5 Z 2 SFK-VO sind allgemeine Angaben über die fachliche Qualifikation der vorgesehenen Lehrkräfte dem Antrag auf Anerkennung der Ausbildung beizulegen, eine namentliche Bekanntgabe der Vortragenden ist nicht vorgeschrieben.

Der vorgelegte Fachausbildungsplan in Form eines blockweisen Lehrganges entspricht den Voraussetzungen des § 1 SFK-VO, die personalen und sachlichen Ressourcen erschöpft die gewährleistet. Der zur Anerkennung beantragte Fachausbildungslehrgang der Sicherheitsfachkräfte der BRVZ Bau-, Rechen- und Verwaltungszentrum Gesellschaft m.b.H. entspricht den Bestimmungen der SFK-VO.

Gemäß § 1 l.V.m. § 4 der Bundes-Verwaltungsabgabenverordnung 1983 ist für die Erfassung dieses im Interesse des Antragstellers getroffenen Bescheides eine Verwaltungsabgabe von 80,- (Schilling sechzig) gemäß Tarifpost 1 zu entrichten. Eine Befreiung der Antragstellerin von der Entrichtung dieser Verwaltungsabgabe ist nicht vorgesehen.

Es war daher sprachgemäß zu entscheiden.

Rechtsmittelbelehrung:

Gegen diesen Bescheid ist ein ordentliches Rechtsmittel nicht zulässig.

Hinweise:

2. Gemäß § 3 Abs. 5 SFK-VO ist das Bundesministerium für Arbeit, Gesundheit und Soziales und das Bundesministerium für Wissenschaft und Verkehr berechtigt, eine(n) Vertreter(in) zur Prüfung zu entsenden und sind daher vom Prüfungstermin zeitgerecht zu verständigen.

7. RISK MANAGEMENT

Does your organization have a program for managing environmental and health & safety risks?

Yes [X] No [ ]
### 7. INSPECTIONS/AUDITS

- Are there regular EH&S audits for a project?
  - Weekly [ ]
  - Bi-Weekly [ ]
  - Monthly [X]
  - Less Often, As Needed [ ]

- Who conducts these audits?
  - Contractor [ ]
  - Insurance company representatives [ ]
  - Third party consultants [X]
  - Other [ ]

- What measures are used to evaluate the effectiveness of EH&S controls?
  - The effectiveness of EH&S controls is monitored by statistical analysis of occurrences/rates/accidents versus empirical data from comparable projects. Trends are regularly monitored and action is taken in case of an adverse trend.
Have any citations been issued to your company in Canada within the last three years from the OH&SA or any other regulatory organization (e.g., Orders to Comply, charges, fines, letters, work refusals etc.)?

Yes [ ] No [X]

If so, by whom and when?

____________________________________

____________________________________

What was the citation issued for?

____________________________________

____________________________________

____________________________________

What corrective actions were taken by Management to address issue?

### 11. ACCIDENT/INCIDENT INVESTIGATION

Does your company have a policy/program for the investigation of accidents/incidents?

- Yes [X]
- No [ ]

*(If "yes" please provide a copy.)*

Please refer to attached Annex F - Example of Accident Investigation Program Manapouri.

Are all workers made aware of this program?

- Yes [X]
- No [ ]

Are all workers encouraged to provide reporting information for this program, if required?

- Yes [X]
- No [ ]

### 12. CORRECTIVE ACTION

Does your company have a program for managing corrective actions resulting from poor performance, inspections, accidents, incidents, etc.?

- Yes [X]
- No [ ]

*(If "yes" please provide a copy of this program.)*

Example of Accident Investigation Program Manapouri

*(Corrective actions are part of the AIP)*

### 13. SAFETY/MEETINGS

Do you hold site safety meetings for field employees (both manual and non-manual)?

- Yes [X]
- No [ ]

How often?

- Weekly [ ]
- Bi-Weekly [X]
- Monthly [ ]
- Less Often, Specify Frequency [ ]

### 14. SAFETY/INSPECTIONS

Do you conduct project safety inspections?

- Yes [X]
- No [ ]

Are these inspections conducted at all levels of management?

- Yes [X]
- No [ ]

How frequently are inspections carried out?

- Weekly [X]
- Bi-Weekly [ ]
- Monthly [ ]
- Less Often, Specify Frequency [ ]

Who carries out these inspections?

Site inspections on a daily basis are the responsibility of the Tunnel Manager, Forman, and Shift Bosses.

Weekly site inspections are performed by the Health and Safety Officer (HSC) jointly with the Tunnel Manager.

The HSO will meet periodically with the Project Manager to review the Monthly Health and Safety Reports and discuss any corrective action required.

How are results documented?

The inspections are recorded on standard inspection forms including the recommended corrective actions. The results are included in the Monthly Health and Safety Report.
15. "TAILBOARD" SAFETY MEETINGS

Do you hold craft "tailboard" safety meetings?
  Yes [x]  No [ ]

How Often?
  Weekly [ ]  Bi-Weekly [ ]  Monthly [ ]  Less Often. Specify Frequency [ ]

16. HAZARDS/JSA'S

Is a Job Safety Plan/Job Safety Analysis conducted at the start of a job?
  Yes [x]  No [ ]

Does the Job Safety Plan/Job Safety Analysis include emergency response?
  Yes [x]  No [ ]

Are hazardous and designated substances listed prior to work commencing?
  Yes [X]  No [ ]

Are controls/plans implemented to mitigate the identified risks?
  Yes [x]  No [ ]

(please refer to attached Annex G - "Example Job Safety Program")

(Please provide a copy of your Job Safety Plan/Job Safety Analysis Program.)

17. KEY HEALTH AND SAFETY PERSONNEL

List key Health and Safety personnel planned for this project. Please list name, expected position and safety performance on last three project (Lost Workday Case Incident - LWCI). When a project has not been specified, list key company personnel.

<table>
<thead>
<tr>
<th>Name</th>

Management System
for implementation of the Group Principals

Safety, Health and Environmental Protection – SCC
Work Safety Information
Work safety Information

Short Version of

SAFETY DIRECTIVES
Work Safety

General

The health and protection of our employees as well as other persons involved are of prime importance.

We are aware that there is a particularly high danger potential when the place of work is changed and no precautions, such as ensuring safety at work and providing protective clothing, are taken.

The management of the operating unit is responsible for the organization of safety provisions.

The safety expert appointed by management maintains the specific programmes for safety and health provisions in his area of responsibility and ensures their observance. These programmes are reviewed by management in relation to their capability.

The procedures for safety and health are mainly regulated by the quality system procedures of the Berufsgenossenschaft Bau - BG and Tiefbau - BG, the Bergbehörde, the relevant laws and codes of the particular country, the company and the quality plan.

Internal Conversion

Safety and health principles are based on, e.g.
- all employees accepting direct responsibility for work safety;
- training to improve work safety;
- organization and equipment of work places and routes taking safety into account;
- protection and securing of danger areas;
- immediate remedy of identified safety defects.

BASIC SAFETY INSTRUCTIONS

CONTENTS

(A) INTRODUCTION
(B) CONDUCT
(C) HOUSEKEEPING
(D) SAFETY EQUIPMENT
(E) HAZARDS
(F) CONSTRUCTION SITES
(G) CONSTRUCTION EQUIPMENT
(H) AMENITIES
(I) ACCIDENT INVESTIGATION
(J) ACCIDENT PROCEDURES
(K) CONCLUSION
PREFACE

The health, welfare and the maintenance of a safe working environment for all employees is a major concern of the STRABAG Group of Companies. This manual has been prepared to ensure that you as an employee, are aware of the group's code of practice and prevention. Read the manual carefully as it may well prevent you or others from becoming seriously injured or could prevent a serious accident.

Remember:

1. Accidents don't just happen - they are caused by carelessness.
2. Safety is never an accident, it is always the result of intelligent effort.

(A) INTRODUCTION

The hazards of the construction industry are more diverse than those in other industries and it is to be realised that one unsafe practice can have disastrous results with often fatal and costly consequences. The provision of safe working areas, safe working practices, the general maintenance of a clean and safe working environment, the operating of equipment in a safe and correct manner and the safe handling of material is the joint responsibility of both the employer and the employee. Safety is the responsibility of all concerned employers and employees, and this manual is intended to provide guidance towards an accident free working environment.

(B) CONDUCT

The manner in which you conduct yourself in the workplace is important to your work mates and will assist in the elimination of work hazards. The following list details some of those aspects of conduct which will not be tolerated by the company and which are unsafe and hazardous acts affecting all personnel on the job.

1. Alcohol will not be permitted on the site.
2. People under the influence of alcohol will not be permitted to work under any circumstances.
3. Fighting, practical jokes, throwing of material etc., or any other act which could lead to injury.
4. Drugs are not to be taken or used on site unless an authorisation for their use by a duly qualified medical practitioner can be produced.

(C) HOUSEKEEPING

Many accidents result from bad housekeeping. Site tidiness is the foundation of a well run job. To enable the maintenance of good housekeeping at all times, the following procedures are to be recognised and complied with by all employees.

1. All areas are to be maintained free of dangerous projections or obstructions and be reasonably free of fire hazards, debris and other extraneous materials.
2. Storing and stacking should conform to recognised safe practices, be neat, orderly and maintained for ease of access.
3. All work areas, elevated platforms, access ways, ladders and workshops shall be kept tidy, orderly and in good repair.
4. Changing and lunch rooms shall be kept free of extraneous materials such as used paper containers, old newspapers or bottles.
5. Housekeeping to be a daily routine and a supervisory responsibility. It should not only be the concern of a clean-up gang.
6. Grease, oil, or other slip hazard materials shall not be allowed to accumulate on workshop floors or work areas. When spillage has taken place, it must be properly cleaned up immediately.
7. The presence of timber, or other materials with protruding nails and protuberances of a similar nature will not be tolerated. Nails etc. must be removed or made safe before stacking.
8. Tools and other gear shall not be left in a position where they may fall to a lower level or cause obstruction to other persons.
9. Safety equipment is to be requisitioned in detail and in conformity with specifications, company requirements and the appropriate standard codes.
(D) SAFETY EQUIPMENT

1. General

The company supplies hard hats, water proof clothing, gum boots, gloves, goggles, visors, ear muffs and in some cases overalls and safety boots. It is your responsibility to look after this equipment, keeping it clean and in good repair. On termination of employment, all protective equipment issued must be returned.

2. Clothing

Wear clothes that are suitable for the job. Do not wear badly torn clothes as they do not give protection. Flapping clothes are particularly dangerous near moving machines. Coloured vests will be supplied and shall be worn when working around equipment.

3. Head Protection

The wearing of head protection throughout all stages of site construction is compulsory. Personnel operating equipment with protective cabins must wear head protection when outside the cabin of the machine. Any person refusing to observe this practice will be requested to leave the site until compliance is accepted.

4. Footwear

The wearing of light shoes, sandals, thongs, slippers or other fancy footwear is prohibited. Substantial footwear must be worn at all times.

5. Gloves

Gloves are to be worn to protect hands from rough, splintery and sharp objects. It is recommended to wear gloves when working or handling cement, lime, concrete, chemicals and acids.

6. Goggles

Goggles or visors shall be worn when using grinders, compressed air tools (e.g. jack hammers, chipping hammers etc.), welding and cutting equipment, acid or caustic solutions, riveting tools, tools for the chipping of steel, concrete, bricks etc. and any other operation that could cause damage to the eyes. Never look at a welding arc without protective eye glasses or shield.

7. Hearing Protection

Hearing protection shall be worn in all designated noise areas. The following short list gives an indication of some hazardous processes, however in doubt consult the site or workshop foreman.

(a) Electric Saws
(b) Percussion Drills
(c) Jackhammers
(d) Bench Saws
(e) Grinders
(f) Hammering in confined areas.

8. Lifting

Many serious and painful injuries are caused by attempting to lift loads that are too heavy or awkward. These injuries can be avoided by observing and following the precautions as listed:

(a) Test the load, if it appears to be too heavy or bulky obtain some assistance from a fellow worker or use mechanical means.
(b) Bend the knees and keep the back straight. This places the strain on the leg muscles and reduces the pressure on your weaker back muscles.
(c) Prevention is better than cure, always seek assistance if in doubt.
(E) HAZARDS

1. Air Tools

Care should be taken to ensure that hoses carrying compressed air are secured at the free end so that injuries are not caused by a whipping hose. It is important to check hose fastenings on a regular basis.

2. Excavations

Excavations and/or trenches exceeding 1.5 metres in depth may require shoring to both walls and faces, or some other alternative as required by regulations. Proper access shall be supplied to allow movement to and from all trenches and excavations. All projects containing excavations and/or trenches exceeding 1.5 metres in depth, shall be under the control of a foreman.

3. Explosives

Explosives shall be stored and used in accordance with the State or Local Laws and Regulations. Authorised and qualified personnel only are to handle and use explosives.

4. Hand Tools

All hand tools to be maintained in a safe working condition. Only use the tool for the function for which it is designed, other uses are invariably dangerous. All tools should be properly stored when not in use. All electric hand tools shall be insulated, properly earthed, and maintained. Any malfunction or defect to electric hand tools should be reported to your foreman and the tool returned to the store for repairs.

5. Power Tools

All power tools to be maintained in a safe working condition. Prior to use of any power tool a check should be made to ensure that:

(a) Electrical fittings are secure
(b) Safety guards are in position
(c) Machine is switched off prior to activating electricity supply
(d) Ensure all attachments and fittings are matched to the power tool and that the tool is used for the purpose for which it was designed.

Explosive power tools SHALL NOT be used unless you have obtained a licence stating your competency to do so (piston powered tools are exempt from this requirement). It is imperative to place notices and signs designating the area of operating of this equipment. No tool should be left in a loaded condition. These tools should only be loaded immediately prior to use.

ALWAYS WEAR THE CORRECT PROTECTIVE EQUIPMENT WHEN USING POWER TOOLS

When using electrical equipment, the following conditions are to apply:

(a) All power leads should be raised above floor level
(b) All repairs to electrical equipment, leads and power boxes must be carried out by a qualified electrician
(c) The use of double adaptors on any site should be limited to one per outlet. Piggy backing is prohibited.
(d) Always assume that electrical wire and equipment is alive and treat it with caution and respect.
(e) All damaged electrical installations, wiring and equipment should be removed from service and reported immediately to a qualified electrician or site manager.
(f) Never attempt to extinguish any electric fire with water or a water based extinguisher.
(g) Power tools are not to be used on leads extending more than 36 m from the power box. Power leads are not to be extended to another floor from the floor on which the power box is situated.
6. Machinery Guards

Guards for your protection are included in the design of most machinery. It is imperative that NO GUARDS ARE REMOVED from any machine for any reason other than maintenance. Always check to ensure that any equipment under your control has the appropriate guards, if not it shall be returned to the store for rectification. Ensure the machinery cannot inadvertently be started whilst maintenance is being carried out.

7. Welding and Cutting

Welding and cutting are not permitted on days of Total Fire ban unless a permit has been first obtained from the relevant Fire Authority and all conditions of that permit have been complied with including all necessary fire prevention requirements. Cylinders shall be tied/chained in a vertical position with the turn off/on key attached at all times during use. Empty cylinders shall be plainly marked and treated with caution as some gas may still be contained. If cylinders are to be transported by crane or hoist, they shall be carried in a suitable cradle or trolley and be securely fastened. Never lift cylinders using wire or fibre rope slings. When you leave an oxygen welding or cutting torch, turn off the gas at the cylinders and bleed off the hoses through the torch. This will avoid any danger of gas leak if the hose is damaged while you are away. Welding equipment shall not be used by anyone except a qualified operator. Proper eye protection shall be worn at all times when welding or assisting a welder.

(F) CONSTRUCTION SITES

All new employees and other employees not familiar with the particular site SHALL report to the site supervisor. All job area speed limit, hazard and other warning signs shall be observed. Driving vehicles on haul roads will not be permitted unless authorisation has been received from site management. All persons travelling in vehicles on site shall be seated. No travelling or running boards or standing in vehicles will be permitted. Construction haul roads to be kept clean at all times. Any spillage or other debris must be reported to site management to be cleared in a proper and authorised manner. Excavation adjacent to underground services will not be permitted without the approval of site management. When opening up is approved a person on the ground shall be in attendance. No person is allowed to work alone in trenches exceeding 1.2 metres in depth. Excavations near path or walkways shall be barricaded and where necessary equipped with warning lights. All scaffolding and ladders shall be placed and/or constructed in accordance with the relevant Acts. All scaffolding shall only be erected, altered and dismantled by persons who are the holders of a current certificate of competency as a scaffolder issued under the relevant act. All scaffolding is to be maintained in an efficient state. Scaffolding is provided for your benefit and is to be used. Kick boards shall be placed around all scaffold platforms and walkways. No running on the site will be permitted unless in an emergency.

(G) CONSTRUCTION EQUIPMENT

Mobile equipment shall be provided with adequate warning devices, such as back up alarm, front and rear lights, where applicable etc. and shall be maintained in an operable condition at all times.

1. Operating Equipment

Only persons duly authorised by the Company are permitted to operate equipment. Safety belts where fitted shall be used. Exercise care when getting on or off equipment. Use footsteps or ladders where provided. Jumping off a machine is not permitted. Ensure cabins and controls are clean and free from rubbish and debris. Oil and grease spillage to be cleaned off cabin floor, foot rungs, ladders etc. Always look behind when reversing. Ensure that where reverse warning systems are installed they are in working order, if not immediately report to supervisor. Take care when working in vicinity of personnel working on the ground. Where loads are to be lifted, do not swing over men at work. Take extreme care when operating in the vicinity of overhead structures, particularly power lines, remember “Look Up and Live”. Lifting with cranes or excavators will not be permitted unless fitted with an approved safety device. Pneumatic percussion drills shall be fitted with water storage and supply lines to limit the emission of dust from the drill hole.
2. Working in Vicinity of Equipment

When working around an item of equipment advise the operator of your presence. Under no circumstances walk behind moving equipment or under the jib of a crane or excavator. Avoid working on the blind side of equipment, if this cannot be avoided, ensure that the operator is aware of your presence. Under no circumstances will personnel, other than the operator, be allowed on working equipment unless authorised by the Company.

(H) AMENITIES

Mess and changing facilities are provided for your use and convenience. These rooms to always be maintained in a clean and tidy condition. Your assistance in maintaining these amenities will help provide a clean and hygienic place for the consumption of food during rest breaks. Food scraps and other rubbish shall be placed in the receptacles provided. Toilet and washing facilities shall always be maintained in a clean and tidy condition. Under no circumstances will misuse of these facilities be permitted.

(I) ACCIDENT INVESTIGATION

It is most important that all accidents be reported immediately to site or company management and a format report filled in. Investigation of injuries and how they were incurred will be carried out to assess current work practices and changes formulated if necessary to ensure a safer working environment.

Your assistance in providing the accurate information required to complete the necessary reports will lead to the elimination of any potentially unsafe conditions and practices which may develop.

(J) PROCEDURES TO BE ADOPTED IN THE EVENT OF SERIOUS ACCIDENT

1. Do not panic.
2. Ensure there is no impediment to the injured person's breathing. If possible place person on side in coma-position to avoid choking or swallowing tongue.
3. Contact Foreman and/or Safety Officer.
4. Ensure the exact location of accident is given to all persons involved in rendering assistance to the injured person.
5. Do not move injured person unless he/she is in threat of further danger.
6. If the injury involves excessive bleeding, apply pressure to area to reduce blood loss.
7. Attempt to keep injured person calm and warm.
8. In the case of electrical accidents it is imperative to release the person from the electrical current:
   (a) Locate the source and turn off.
   (b) If this is not possible, attempt to remove person from the source of the electrical current by the use of non-conductive material, e.g. timber stick.

   UNDER NO CONDITIONS TOUCH THE PERSON WHILST CURRENT FLOWING!

9. In case of electrical fire do not use water or liquid based extinguishers to extinguish.

(K) CONCLUSION

The foregoing provides a basis upon which the company will carry out and expect all employees to carry out the detailed working practices which will enable the working environment to become safer and satisfying in future years.

It is hoped that it will assist the employee to recognise, understand and control the hazards of his job.

Every accident, every injury and every serious incident is a symptom of some inadequacy in the system. It is the intention of the company and our expectation that all employees will, wherever possible, identify and eliminate this inadequacy.

The company will require co-operation to enable the combined improvement of both production and accident prevention methods at all levels.
Management System
for implementation of the Group Principals

STRABAG AG  September 2004
Management System for implementation of the Group Principles

As per June 2004
Scope of Application: Group
Put into Force: BHS Board
Responsible for the contents: MS Co-ordination Committee
Group Principles

Organisation and Management
Employees and Resources
Business Activities
Measurement, Analysis and Improvement

This Management Manual describes the system for implementation of our Group Principles in all companies of BAUHOLDING STRABAG AG.

The Boards of Directors commit themselves and the management to supporting the Management System and to providing the resources for further development of Quality Assurance, Work Safety, Environmental Protection and the Management System as such.

All employees are obligated to organise and perform their tasks and duties in accordance with the guidelines specified in this Management Manual.

For the BHS Board

Signed Dr. Hans Peter Haselsteiner

Vienna, 24 June 2004
GROUP PRINCIPLES
Our Group Principles provide the basis for the objectives, strategies and entrepreneurial activities.

Economic Success
In responsibility to our shareholders, customers, employees, suppliers, subcontractors and society, our prime aim is to ensure economic success on a long-term basis.
Targeted activities, early identification of chances and risks and their responsible consideration safeguard the continuity of our companies and protect our shareholders' interests.
Owing to systematic and constant improvement, we will also be able to meet the growing challenges of the future.

Customers
Our activities are focused on satisfying our customers' justified requirements and expectations.
We meet market demands through close customer contact, professionalism, innovative ideas, and competitive prices.
A frank exchange of information and experience with our business partners is also foreseen within the framework of our strategies and objectives, whereby we ensure the required degree of confidentiality and discretion.

Employees
In order to meet our corporate objectives, we rely on competent and efficient employees. We promote the level of know-how within the Group by professional development and training, support the personal development of our employees and provide adequate information and suitable working conditions.
Our employees keep themselves well informed, while harmonising their own objectives with those of the Group and giving Group interests priority.
The health and safety of our employees and all other parties to our activities are among our main concerns.

Suppliers and Subcontractors
For the purpose of furthering quality and the economic efficiency of our services, we also count on the experience and capacities of carefully selected suppliers and subcontractors.

Social Awareness
We respect human rights and promote public welfare.
We observe existing laws and recognise the rules of fair competition.
We are aware of our environmental responsibility. In the execution of our supplies and services, we make every effort to use energy and natural resources economically and reduce noxious emissions and waste.

The BHS Board's stated strategic objective for the 2003 - 2006 planning period:

"Achieving and/or maintaining market leadership in all defined markets and business fields by cost leadership, employee qualification and motivation, and innovative initiative."

Management System Co-ordination Committee of

BAUHOLDING STRABAG Aktiengesellschaft and the

Management System Representative in the Country

The Management Manual is subject to revision
ORGANISATION AND MANAGEMENT

Organisational Structure

Under the auspices of BAUHOLDING STRABAG Aktiengesellschaft, controlling company of the Group, legally independent 'country' companies act in the market within the framework of the overall international organisation.

The Business Field represents the main Group structuring criterion.

The organisational structure permits close to market decisions and provides the co-ordinated and controlled management required for achieving Group objectives. It is detached from commercial law structures.

Abbreviations: D...Germany, A...Austria, OE...East Europe, Evol...Evolution, H...Hungary, CZ...Czech Republic, PL...Poland, SK...Slovakia, HR...Croatia, Int.Proj...International Projects
Business Fields and Fields of Activity

The range of services of the business fields covers all stages of the construction process. The business fields provide coordinated and complementary services.

Allocation of the various spheres covered in the fields of activity to the business fields must be implemented on a blanket coverage basis and adhered to. Regional changes to the allocation can only be undertaken with the agreement of the responsible business fields’ boards.

Ideally, project acquisition, planning and execution are performed after consultation and in co-operation with partners from within the Group.

Project acquisition across regional borders requires the agreement of the respective BHS Board.

Co-operation with internal partners, customers or subcontractors is contractually agreed.
Management Structure

The BHS Board practices uniform management, and is responsible for maintaining financial equilibrium throughout the Group and safeguarding Group interests.

After consultation with Division Managers, the Board also determines their programme and defines Group strategic objectives.

For management, co-ordination and control of the Divisions or of Sub-divisions reporting directly to the Board (without going through Division Management), the Board acts on the basis of business activities requiring consent.

Within the framework of Group business policy, Division Managers carry out their business independently and on their own responsibility, i.e. it is incumbent on them to achieve objectives defined in the strategic and operative planning and realise the individual measures prescribed.

All operating business is undertaken by the Sub-divisions. They are responsible for the best possible result in the regional markets allotted to them and are usually managed, co-ordinated and controlled by Division Managers.

The supervision of managers of Sub-divisions reporting directly to the Board is the concern of the BHS Boards responsible.

The service companies are organised in Central Business Units and operated by Sub-divisions. Within their area of responsibility they work independently from the operative Divisions and Sub-divisions, with the Central Business Manager being responsible for co-ordination of the regional service companies.

Interfaces and co-operation between service companies and operative units are regulated with service agreements.

Responsibilities, assignments and authorisations of the Boards, Division Managers and Sub-division Managers are defined in the business rules of procedure.

The functions’ objectives, and operating and management work within the Sub-divisions are laid down in descriptions of the functions.

For assurance and further development of the Management System representatives are appointed as follows:

<table>

Company Management

Planning and Controlling

Strategic and operative planning and controlling represent the main Group management instruments.

Strategic planning is aimed at long-term improvement of the market position and construction services and products offered by the targeted use of personnel, financial and technical resources. Sources of loss should be eliminated, existing profit potentials strengthened and new ones identified.

Developed on the basis of analyses, the strategic concept, in which the strategic objectives and planned measures with the respective resources requirement and effects on performance are presented, is approved by the BHS Board after assessment and, if necessary, adjustment.

The strategic framework is rounded off by operative planning comprising foreseen short and medium term business policy targets and measures.

Before the end of the year operative planning for the following year is prepared by the Sub-division / Division Management and approved by the BHS Board in the month of January of each year after planning meetings with the Division and/or Sub-division Managements with direct reporting access.

Methodically harmonised with the above, controlling follows current business development in the comparison of target and performance.

Assessment

When undertaking Group assessment, the main indicative figures are compared with targets agreed for the respective planning period. Deviations are analysed and assessed and, if necessary, corrective action taken.

Improvement potential is highlighted and used for continuous further development. Analysis and improvement of the Management System is a component of the Group assessment.
Internal Communication

Internal communication and information flow are achieved within the defined structure of committees under agreed chains of information through minutes, reports and electronic information systems. Communications outside the chain of information are identified by source and responsible function.

Group Guidelines

The Management System is documented in the Management Manual and further guidelines.

Management Manual

Further Guidelines

- Internal Agreements
- Resolutions of Group's Board of Directors / Business Field Boards
- Group Guidelines / Procedures
- Resolutions of Division Managers
- Rules of Procedure according to Organisational Structure of the Group
- Service Agreements between Service Companies and Operating Units
- Resolutions of Sub-division Managers
- Directives issued at particular management levels

All guidelines can be identified by titles, dates of issue and, if necessary, number. Applicable guidelines are integrated into the Management System by the respective representative.

Employees and Resources

Employees

The systematic recruitment of qualified and competent employees, their promotion and the support of their personal progress through professional development and training are effected based on a pre-determined procedure. Major personnel development phases include:

- Human Resources Planning
- Recruitment
- Introduction and Orientation
- Consultations, Development and Succession Planning
- Training

A defined distribution of tasks and co-operation between operating units and BRVZ – Human Resources – ensure effective results.

In order to maintain and develop the Management System, the representatives responsible for quality management, health and safety, environmental protection, hazardous materials etc. are trained, employed and authorised in accordance with their sphere of responsibility.
Information

In addition to internal agreements, information also consists of statutes, regulations, standards, guidelines and market and trade data. For effective use of data and resulting information acquisition, transfer, assurance and confidentiality together with the respective terminology are defined as required.

Infrastructure

To ensure effective performance by the operating units and economic efficiency throughout the Group, Central Business Units and Staff Units with cross-border competence are answerable to the BHS Board. These have no authority to issue directives to Divisions or Sub-divisions reporting directly to the Board. Matters of importance are harmonised by the managers of both Central Business Units / Staff Units and Division Management. Assignments performed by the Central Business Units and Staff Units under BHS Board supervision:

BMTI (Central Business Unit)
Plant and equipment management (investment policy, leasing and repair management, plant systems, form work management)

BRVZ (Central Business Unit)
Annual financial statements, taxes and accounting, finance, Group controlling / risk management / insurance / real estate, personnel, information technologies

TPA (Central Business Unit)
Technical development policy (quality management / quality assurance, technical know-how / research and development), management systems.

Audit Department (Staff Unit)
Control of all entrepreneurial function areas and systems with regard to regularity, expedition and profitability, technical-commercial checks of estimates and construction orders, cartel investigations.

Work Environment

In order to provide our employees with suitable prerequisites for efficient performance and to fulfil the statutory requirements regarding health and safety and environmental protection, we monitor and maintain the required work environment. Construction sites, operational facilities together with their premises and installations, operating procedures, plant and equipment including their erection and provision, utilisation and maintenance comply with the statutory and occupational medical requirements as well as accident prevention regulations. Responsibilities and procedures are organised and documented in accordance with the relevant national requirements.

Construction Plant and Equipment

In order to perform services and produce materials economically and as required, we ensure that construction sites and production facilities are provided with suitable and reliable plant and equipment. Test and measuring devices are subject to regular monitoring.

BMTI units and locations with their REP workshops, service BOXes and mobile workshops are at the disposal of the operating units on an international basis providing management, maintenance, inspection and repair services and also profitability control for plant and equipment.

Procurement

The aim of procurement is to ensure timely and economic provision of products and services in the desired quality, as well as commitment of subcontractors, service providers and suppliers by long-term partnerships.

The operating units are responsible for procurement, if necessary supported by a central procurement management.

To ensure the success of our services and thereby customer satisfaction, the following activities are performed and documented:

- Clear and complete description of services and products to be procured
- Qualification and (initial) selection of subcontractors, service providers and suppliers
- Agreement on acceptance criteria for products and services
- Systematic evaluation of subcontractors, service providers and suppliers as a decision support for future contract awards.
BUSINESS ACTIVITIES

Our customer-oriented business activities are the source of our company's success.

Our objective is to create added value through our activities on the construction market.

Our business activities are aligned and planned based on the Group Principles, strategic targets, and requirements resulting from corporate planning. Consequently, their efficiency is evaluated through the analysis of revenues.

Our business activities comprise:

- Acquisition of market data
- Development and marketing of projects
- Realisation of projects
- Production of building materials and components
- Operator/concession models

They are rounded off by fulfillment of our customers' requirements and optimal customer support services.

In the Building sector, Strabag teamconcept integrates the customer as partner during all phases of a project.

Our business activities are performed in accordance with determined responsibilities and documented procedures with planned targets and tasks including related performance criteria.

The procedures are controlled technically, commercially and legally, utilizing amongst others controlling tools.

Relevant data are recorded.

Building, Road Construction, Tunnelling, Civil Engineering

Added value is achieved mainly through development of technical design and execution of construction contracts.

Processes
- Acquisition / Tendering
- Execution / Production, Warranty and Customer Service

Acquisition / Tendering
The aim is to prepare offers which are profitable for the customer and the company, convince the customer and lead to the award of contracts.

Acquisition / Tendering comprises:
- Marketing / acquisition
- Review of documentation received from the customer regarding completeness, discrepancies and feasibility
- Technical, commercial and legal review of documentation regarding requirements listed
- Evaluation of the effects of contractual obligations on quality, deadlines and costs
- Determination of production costs
- Determination and listing of risks and opportunities, definition of surcharges for risk and profit
- Documentation of processes and results of contract reviews and estimation in order to ensure traceability of all pricing factors

Within the limits of the reporting obligations, the Business Unit concerned decides on acceptable projects.

Enquiries exceeding the core interests and capacities of the Business Unit are placed within the Group by the Sub-divisions in order to provide competent customer support at this very early stage.

Successful acquisition / tendering is concluded by preparation of the contract estimate.

Efficiency of acquisition / tendering is measured by the ratio of tenders submitted and contracts awarded.

Taking into consideration the targets determined in the corporate planning, further parameters may be evaluated.

Execution / Production, Warranty and Customer Service
The aim of job execution is to hand over the project to the customer in compliance with the contract, without defects, on time, and within the economic objectives for the project.

Depending on the requirements of the project, the working design is performed by the operating unit, supported by internal service companies or subcontracting to external design offices.

Subcontracted and / or customer-provided design services are reviewed in terms of completeness, technical feasibility, economic efficiency, and deadlines.

In order to create suitable conditions, the required works processes, responsibilities and resources are already determined during works planning:
- Ensuring information status of the persons responsible for execution of the work during an internal commencement meeting / kick-off meeting,
- Inspection and test plans and tests according to quality characteristics,
- Monitoring of costs and deadlines based on periodic performance and progress reports,
- Controlling action in case of deviations from target figures,
- Identification and processing of amendments / additions to the contract.

Adequate project documentation including monitoring of subcontractors’ performance ensures traceability of relevant project data.

Risks, opportunities, defects and measures identified during project review and/or analysis of project data are evaluated and passed on to the respective functions.

Efficiency of performance is measured by adherence to deadlines and fulfillment of technical requirements, without exceeding the budget costs (work estimate).

Customer satisfaction is monitored systematically and evaluated by the managers in accordance with the management structure.
Project Development
Infrastructure
Added value is achieved through acquisition of additional contracts by developing infrastructure projects (transportation, power and waste management) including the procurement of funding and contract management in the realisation, operation and marketing.

Processes
• Selection and Definition of Projects
• Development, Tendering and Contracting
• Realisation, Warranty and Customer Service
• Operation and Maintenance, Marketing

Business activities are performed in close co-operation with operating Group partners, observing the reporting obligations towards the Board of Directors.

Achievement of the overall target is measured by the degree of customer satisfaction and the rate of return.

Project Development
Building
Added value is the result of development, design, realisation, successful marketing and, if required, operation of immovable property.

Achievement of the overall target is measured by the degree of customer satisfaction and the rate of return.

Processes
• Development
• Design and Planning
• Preparations for Realisation
• Realisation, Warranty and Customer Service
• Operation and Maintenance, Occupancy

The business activities are carried out in close co-operation with operative partners within the Group, based on predetermined procedures.

Process and results of individual stages are evaluated and controlled by comparison with the specified targets.
MEASUREMENT, ANALYSIS AND IMPROVEMENT

We measure the results of our processes and the achievement of our aims. Following analysis and evaluation, control and/or corrective measures are implemented where necessary.

Preventive and Corrective Action

Preventive and corrective actions shall ensure safeguarding or quick re-establishment of target conditions in respect to processes and systems.

Preventive measures are undertaken in particular in the field of work environment, environmental protection, and risk assessment during tendering, contracting and work planning.

Measures and results are recorded and passed on to the responsible functions for evaluation.

Improvement Process

By means of programmes and activities, we raise the level of performance, processes, systems and internal structures (infrastructure, information, communication) in order to further develop the company.

Targets, measures and results are recorded and passed on to the responsible functions for evaluation.

Proposals for Improvement

A documented procedure gives all employees the opportunity to make proposals and submit ideas for improvement, rationalisation, simplification and facilitation of operations, increased profitability of the company, increased work safety, or improved quality of our performance and supplies.

Inspections

Process performance is monitored through inspections.

In accordance with the contract and for the purpose of a responsible internal quality control, inspections are performed as follows:

- Inspections upon receipt of materials/equipment in order to verify conformity of both procured or customer-provided performance and supplies.
- In-process inspections, if processes do not permit later inspections or risks can be detected and minimised at an early stage.
- Final inspection of the contracted performance/supply prior to handing over to the customer.

Administrative Audits

As part of the risk management, process-independent and neutral internal administrative audits are performed to detect and avoid risks and assess the legality of our processes.

These assessments are performed during both tender stage and execution of construction works, in accordance with documented selection criteria.

Audit reports are distributed to the operating units, Division Management, Board of Directors and, if necessary, the public accountant.

Information regarding the Management System is distributed to the Country Representative.

Quality Audits

Quality audits assess the effectiveness of the Management System, determine whether procedures are suitable for the achievement of targets and are observed, and whether the processes can be improved.

Measures and results are recorded and distributed to the responsible functions for evaluation.

Corrective, preventive and improvement actions are monitored and evaluated with respect to their implementation and effectiveness.

3. Safety Regulations for IT Applications
4. Principles of Personnel Development

(2. – 4. are available in German and filed in the data bank under "Management System")

COUNTRY-SPECIFIC ATTACHMENTS
[from page 14]
### Code of Practice

When marked as requiring approval, the following business transactions of the Sub-divisions (Dir.) or Divisions (UB) call for prior consent by the Division Management or the BHS Board, if necessary following agreement with the Central Business Unit Manager.

Applications for approval re. business transactions must be submitted in writing to the Division Management or Executive Board. This is also applicable for lower level Group companies.

Application for approval must be made early enough to allow time for decision making.

Furthermore, certain business activities are marked as being expressly prohibited for Division and Sub-division Managements.

Within the framework of de-central and central reporting to the Division Management or the responsible BHS Boards and/or the regional service companies, Management must ensure that all data are reported in compliance with the dates foreseen throughout the complete organisation using the information and communication paths set up.

In addition, the following reporting obligations must be compiled with:

<table>

CERTIFICATE

IQNet and OQS

hereby certify that the organization

Strabag AG
A-9800 Spittal/Drau, Ortenburgerstraße 27

Scope of application:
Building and Structural Engineering Austria, Building and Structural Engineering International
Road Construction International, Tunnelling International
Civil Engineering and Special Foundation Engineering International

has implemented and maintains a

Quality Management System

which fulfills the requirements of the following standard

ISO 9001:2000

Issued on: 2003-07-14
Validity date: 2006-05-29
OQS certified since: 2000-05-30
Registration Number: AT-1828/1

Dr. Fabio Roversi
President of IQNet

Viktor Seitschek
President of OQS

IQNet

© IQNet 2020
OQS-Certificate

OQS Certification and Evaluation Ltd. awards the
OQS Certificate to the following organisations:

STRABAG AG
A-9900 Sillian/Dova, Oberlaufmgasse 27

Scope of application:
Building and Structural Engineering Audio
Building and Structural Engineering International
Road Constructions International
Tunnelling International
Civil Engineering and Special Foundation Engineering International

The validity of the OQS Certificate will be maintained
via annual surveillance audits and more yearly
removal audits.

Registration No.: 1828/1
Date of initial issue: 30 May 2000
Valid until: 29 May 2004

Weing, 14 July 2003

OQS Certification and Evaluation Ltd.

V. Kienle, President

K. Scheiber, General Manager
Safety, Health and Environmental Protection – SCC
Purpose and Objective
To create the organisational and human resource conditions and ensure availability of the necessary resources for compliance with legal safety engineering and industrial medicine requirements and accident prevention regulations, as well as additional requirements for obtaining and maintaining the "SCC" certificate with regard to:
- building sites and operating sites as well as their rooms and equipment,
- work processes,
- building machinery, plant and equipment, including their acquisition, use and maintenance or construction.

The definition of the necessary steps, responsibilities, standards and results must be viewed as supplementary to the generally valid Management System regulations.

Scope
Organisational units (in Austria) wishing to obtain or maintain an SCC certificate.

Procedure and Responsibilities
See following tables for the sections
1 SHE Policy and Organisation, Management Commitment
2 Hazard Assessment and Evaluation
3 Human Resource Selection
4 Information and Training
5 Safety, Health and Environmental Protection Communication
6 Rules, Regulations, Project Safety Plan
7 Safety, Health and Environmental Protection Audits
8 Operational Health Sector
9 Purchasing and Testing of Machinery, Resources, Materials and Services
10 Reporting, Registration and Investigation of Accidents / Near-Accidents and Unsafe Situations

J. Pippion
Group Coordinator Management System for the reasonable Director

J. Pestal
Industrial Safety Coordinator for Austria

A. Popelak
Management System Officer for Austria

OQS Certificate

OQS Certification and Evaluation Ltd. awards the OQS Certificate to the following organization:

STRABAG AG
A 9800 St. Pölten, Östrichwegasse 27

The OQS Certificate confirms the application and further development of an effective SAFETY MANAGEMENT SYSTEM complying with the requirements of standard SCC.

Scope of application:
Including all Business Units (Groups per unit listed in the appendix)

Registration No.: 07171
Date notified: 14 July 2003
Valid from: 29 May 2006

The validity of the OQS Certificate will be maintained via annual surveillance audits and three yearly renewal audits.

Varnia, 14 July 2003

OQS Certification and Evaluation Ltd.

Annex C
Industrial Safety Information
The Blue Book – Safety at Work
Information Brochure for New Hires
Industrial Safety Information
1. **PURPOSE**

To ensure that the valid laws and regulations and the engineering rules with regard to accident prevention and health protection on building sites are complied with.

2. **SCOPE**

Valid for BAUHOLDING STRABAG AG / Austria/
Valid for Joint Ventures if STRABAG is responsible for technical / commercial management

3. **TERMS AND ABBREVIATIONS**

See CH 3.3-STO-03 - Abbreviations

4. **DESCRIPTION**

4.1. **ORGANISATION**

The Engineer is generally responsible for compliance with safety regulations on the building sites. He shall be assisted by other persons authorised to issue instructions (foreman, assistant foreman, overseer, etc.), whereby such assistance is limited to the work areas assigned to these persons.

Pursuant to the **Industrial Safety Act** the Employer shall, in order to increase the efficiency of safety and health protection, appoint Safety Officers, Industrial Physicians and Safety Ombudsmen as well as First Aiders. Furthermore, three Responsible Officials shall be appointed for the entire Bauholding Strabag AG concern. One Responsible Official shall be responsible for compliance with the **Aliens Employment Act**, one for compliance with industrial safety regulations, and one for compliance with other administrative regulations.

The **Safety Officers** of Bauholding Strabag AG as the Employer's representatives shall be responsible for providing advice and assistance in the field of industrial safety and workplace design to the Direction Head and his executives, the employees, the Safety Ombudsmen, and the Works Council, as well as collaborating with the Industrial Physicians and the Works Council, inspecting the workplaces / building sites together with the Safety Ombudsmen / Works Council for compliance with the safety regulations at regular intervals, and reporting any deficiencies observed thereby to the Direction Head for remediation.

The Direction Head shall appoint a sufficient number of **Safety Ombudsmen** in accordance with the number of employees and the existing safety and health hazards at the workplaces / building sites, and shall notify these to the Industrial Safety Coordinator, who shall notify them to the authority with the approval of the Works Council. Furthermore an appropriate number of First Aiders shall be trained.
The Safety Officers and Safety Ombudsmen shall report to the Industrial Safety Coordinator as the central staff officer for industrial safety at STRABAG. As the responsible official pursuant to § 9, Administrative Penalties Act in conjunction with § 23, Labour Inspection Act, his duty is to continuously improve operational safety on the building sites and in stationary operations within the economically reasonable scope, and to ensure compliance with laws and regulations. He is authorised to issue instructions for this purpose.

Duties of the Coordinator:

- Central concept design, consulting, assistance and coordination in all issues of safety engineering
- Monitoring of compliance with laws / regulations and documentation (see CH 3.4-STO-01 – Safety Engineering Checklist for Safety Officers)
- Evaluation and forwarding of information to the responsible offices
- Cooperation with authorities and accident prevention services
- Planning of accident prevention programmes
- Preparation and maintenance of statistics, as well as analysis and evaluation
- Information, training and instruction
- Organisation of Industrial Safety Committee meetings in the Directions (as required) and in the Group (at least 1x/year)

4.2. Objectives of Industrial Safety

Primary Corporate Objectives:

- Compliance with valid laws and regulations
- To reduce the number of accidents at work / occupational diseases
- To minimise risks
- To promote self-responsibility / motivation, and to train all employees in order to improve industrial safety
- To remedy any observed safety deficiencies without delay and to develop measures for improvement
- To improve the corporate image
- Customer satisfaction

4.3. Safety Planning

During the work preparations for a new building site, the potential safety risks shall already be assessed and safety-relevant workflows shall be planned in such a way that the safety and health hazards are minimized for all employees working on the building site.

Generally, this shall include the following steps:

- Preparation and evaluation pursuant to § 4, Industrial Safety Act – see ÖBEV / EDP programme
- Early coordination with the Labour Inspector – working hours, hazardous work, responsible supervisors, etc.
- Alarm plans for accidents, fire, flood, definition of escape routes, emergency lighting, fire safety, ventilation, firefighting, etc.
- Installation survey
4.4. CONSTRUCTION WORK

All construction works on the building site shall be coordinated with the corporation, subcontractors and other external suppliers on a permanent basis to exclude any mutual hazards.

Basically, the following must be observed:

- Report to the Labour Inspector (building sites > 5 workdays)
- Laws that must be made available to the workers must be posted visibly
- AUVA folder "Safety on the Building Site" must be kept available in the manager's office
- Evaluation pursuant to § 4, Industrial Safety Act
- Instruction of the building site workers and responsible executives of the SUB on existing project requirements (FB 3.4-STO-02)
- Appointment of a deputy in the event of absence of the supervisor (FB 3.4-STO-03)
- Nomination of the required number of Safety Ombudsmen and First Aiders
- Maintenance of the "Building Site Checklist" POL / VA pursuant to CH 3.4-STO-02
- Securing of the building site as set out in the permit notice or relevant ordinance
- Sufficient illumination and ventilation of the workplaces
- Production and maintenance of safety barriers
- Posting of the alarm plan for accidents / fire
- Observation of the ban on juvenile employment, maternity regulations
- Compliance with the Aliens Employment Act (see Data Sheet Aliens Employment issued by the legal department at BRVZ).
- Act to combat illegal employment –
- Accident reports analogue to "Reporting Plan for Work Accidents" as set out in CH 3.4-STO-03

4.5. SAFETY EQUIPMENT

The Employer is under obligation to provide all the safety equipment required on building sites by law, such as:

Personal protection equipment:
Protection for the head, ears, eyes, respiratory system, skin, hands, feet, against weather, waterproof clothing, lifebelts, safety ropes.
Fencing and protection of the building site from unauthorised access, etc.
First Aid:
First aid kit, stretcher, rescue equipment, etc.

Fire safety:
Sufficient fire extinguishers, extinguishing water connections, gas detector, fire doors, etc.

Safety Engineering Inspections and Certifications:
See list of equipment on building sites + Annex

Licenses for activities requiring permission:
Driving license, crane operating license, internal driving permit, blasting permit, etc.

4.6. SAFETY TRAINING

The training as Safety Officer (288 hours), Safety Ombudsman (24 hours) and First Aider (16 hours) shall be provided within the scope of the training programme of BRVZ Academy.

In addition, one-day training on the principles of industrial safety, principles of evaluation and coordination of construction works is offered.

Stand: April 2003
Vermeidung von Absturzunfällen

Der Absturz von erhöhten Standplätzen ist die häufigste Ursache von schweren und tödlichen Arbeitsunfällen auf Baustellen.

Wann sind Maßnahmen gegen Absturz gesetzlich gefordert?

* Bei Öffnungen in Decken und im Boden (Installations-, Lichtkappeneinlungen, Schächte, Künften, etc.),
* an Stiegenläufen und Wandöffnungen über 1 m Absturzhöhe,
* an Arbeitsplätzen und Verkehrswege über Gewässern (oder Stoffen, in denen man versinken kann),
* bei Dacharbeiten über 3 m Absturzhöhe,
* an allen übrigen Arbeitsplätzen und Verkehrswege über 2 m Absturzhöhe.

Welche Maßnahmen gegen Absturz gibt es?

Primäre Absturzsicherungen

verhindern den Absturz von Arbeitnehmern und Gegenständen:
* Abdeckungen von Öffnungen, Abdeckungen müssen tragfähig und unverschiebbar ausgeführt sein

Umwehrungen an den Absturzkanten

(Dreckkanten, Gerüstlagen, etc.) bestehend aus Brust-, Mittel- und Fußwehren,
Brustwehren: in mindestens 1 m Höhe (Ausnahme: bei Fensteröffnungen ist eine Parapethöhe von 85 cm ausreichend)
Fußwehren: mindestens 12 cm hoch
Mittelwehren: zwischen Brust- und Fußwehr, der lichte Abstand beträgt maximal 47 cm

Abgrenzungen durch Brustwehren in 1,00 bis 1,20 m Höhe,
Abgrenzungen sind bei Loggien und Balkonen an den Zutrittsöffnungen, ansonsten generell in ca. 2 m Entfernung von der Absturzkante anzubringen.

Sekundäre Absturzsicherungen

Wenn primäre Absturzsicherungen aus arbeitstechnischen Gründen nicht verwendet werden können, müssen sekundäre Absturzsicherungen, die abstürzend Arbeitnehmer und Gegenstände abfangen sollen, verwendet werden:

Fanggerüste
ausgebildet als Ausschussgerüst, als Konsolegerüst oder in Verbindung mit einem Dachschutzgerüst.

Fangnetze
vorzugsweise im Hallenbau empfohlen.

Dachfanggerüste und Dachschutzblenden.

Sprengarbeiten

Tätigkeiten, die als Sprengarbeiten gelten
- Ausgeben von Sprengstoffen und Zündmitteln aus dem Betriebslager
- Transportieren der Sprengmittel vom Betriebslager zur Verwendungsstelle und zurück
- Verwahren der Sprengmittel in der Nähe der Verwendungsstelle
- Laden und Besetzen
- Herstellen und Prüfen des Zündkreises
- Abtun der Schlüsse
- Beseitigen von Versagen
- Vernichten von Sprengstoffen und Zündmitteln

Bei Sprengarbeiten dürfen nur die dafür unbedingt notwendigen Personen anwesend sein!

Allgemeine Ausbildung für Sprengarbeiten

Besondere Ausbildung für bestimmte Sprengarten
Bestimmte Sprengarbeiten dürfen nur von einem Sprengbefugten ausgeführt werden, der darüber eine besondere Fachausbildung abgeschlossen hat. Dies ist für folgende Sprengarbeiten notwendig:
- Tiefbohrloch sprengung
- Unterwassersprengung
- Sprengen in Serien-Parallelschaltung
- Lawinensprengung
- Sprengen von heißen Massen und
- Metallsprengung

Arbeiten, die der Sprengbefugte selbst ausführen muss:
- Unterweisen der Sprenghilfen und Absperrposten
- Überwachen der Arbeit der Sprenghilfen
- Sprengstoff- und Zündmittellager beaufsichtigen
- Begleiten des Transports von Sprengmitteln
- Verwahren des Schlüssels zum Tagesmagazin bzw. zur Schießkiste
- Prüfen der elektrischen Zünder auf Stromdurchgang und Stromwiderstand bzw. der Brenndauer der Zeitzünderkäufe
- Verbinden der Sprengkapsel mit der Zeltzündschnur bzw. Einbauen des Sprengverzögerers in die Sprengschnur
- Fertigmachen der Schlagpatronen oder Zündpatronen
- Beseitigen der Schlagpatronen oder Zündpatronen
- Festlegen des Streubereiches und die Anordnung der Absperrungen
- Prüfen der Zünderdrähtverbindungen
- Verwahren des Zündmaschinenschlüssels bzw. der Zündmaschinenkurbel
- Prüfen der Zündmaschine

Manchmal genügt die Ausbildung zum Sprengbefugten allein nicht.

Der Sprengbefugte hat viel zu tun.
Sprengarbeiten

- Prüfen des elektrischen Zündstromkreises mittels Zündkreisprüfer
- Anordnen der Sprengsignale
- Verbinden der Zündmaschine und der Zündleitung
- Betätigen der Zündmaschine
- Sprengstoff nach dem Abtren auf nicht detonierte Sprengstoffe untersuchen
- Feststellen, Kennzeichnen und Beseitigen von Versagern
- Auflasen von gefrorenen Sprengstoffen
- Vernichten von Sprengstoffen und Zündmitteln

Sprenggehilfe
Sprenggehilfen sind befugte Hilfekräfte, die ein Sprengbefugter zu den Sprengarbeiten heranzieht, die er nicht selbst verrichten muss. Sprenggehilfen müssen mindestens 19 Jahre alt und in jeder Hinsicht verlässlich sein. Darüber hinaus sind Sprenggehilfen vom Sprengbefugten über die Ausführung ihrer Arbeiten und die damit verbundenen Gefahren zu unterweisen.

Sprenggehilfen dürfen nur die ihnen vom Sprengbefugten übertragenen Arbeiten ausführen. Auch sie haben dabei mit Umsicht und unter Beachtung der notwendigen Sicherheitsmaßnahmen vorzugehen.

Streubereich
Der Sprengbefugte muss dafür sorgen, dass bei Sprengungen niemand gefährdet wird. Bei der Festlegung des Streubereiches ist auf die Streuweite der Sprengstoffe und auf die Druckwirkung zu achten (z. B. bei Verwendung von Auflegersprengstoffen die maximale Ladenumenge pro Zündzeitstufe beachten – siehe mitgeliefertes Sprengstoffmerkblatt).

Falls bei Sprengungen über Tag keine Deckungen zur Verfügung stehen, muss der Streubereich mit mindestens 300 m festgelegt werden (bei Metallsprengungen mit mindestens 1000 m). Der Sprengbefugte hat außerdem zu veranlassen, dass der Streubereich von Wampagen abgesperrt wird. Dazu sind nur verlässliche Personen heranzuziehen, die über ihre Aufgabe besonders belehrt werden müssen. Wampagen sind mit roten Fahnen, Armbinden, Funkgeräten und Schutzhelmen auszustatten. Beenden sich elektrische Leitungen, Bahn-, Seil-, Sende- oder Radaratelien im Streubereich, ist der jeweilige Anlagenbetreiber zu verständigen, um die notwendigen Maßnahmen gemeinsam zu veranlassen.

Streubereich
mit Wampagen absperren!
Sprengstoffe und Zündern

Verwenden Sie nur Sprengstoffe und Zündern, die befördlich zugelassen und in ordnungsgemäßen Zustand sind. Überprüfen Sie vor der Ausgabe den ordnungsgemäßen Zustand. Verdorbene Sprengstoffe und schadhafte Zündern müssen ausgeschieden und sachgemäß verworfen werden.

**Zündern**

**Sprengkraftige Zündern**

- Sprengkapseln
- Sprengschneid
- Sprengverzögerer
- Elektrischer Sprengzünder (Moment- und Zeitzünder)
- Elektronischer Sprengzünder
- Shock-Star-Zündern

**Nicht sprengkraftige Zündern**

- einfacher elektrischer Zünder
- Zeitzündschneid
- Oberflächenverzögerer für das Shock-Star-Zündern

**Besonderheiten bei Zündern**

Zündern müssen grundsätzlich schonend behandelt werden. Darüber hinaus sind sie vor Frost, Feuchtigkeit und Nässe zu schützen.

**Zulässige Zündungsarten**

<table>
<thead>

</tbody>
</table>

**Nur zugelassene Stoffe und Mittel in ordnungsgemäßem Zustand verwenden!**
Sprengstoffe und Zündmittel

Maßnahmen bei elektrischen Zündern

Die Auswahl der Zündmaschine richtet sich nach Zünderart, Anzahl der Zünder und Gesamtwiderstand des Zündkreises.

Der Widerstand des Zündstromkreises darf den auf der Zündmaschine angegebenen höchstzulässigen Widerstand (Grenzwiderstand) nicht übersteigen.

Geräte, Hilfsmittel und Werkzeuge

Geräte, Hilfsmittel und Werkzeuge

Werkzeuge und Hilfsmittel für Pulversprengmittel müssen aus nicht Funkenziehendem Material (Holz, Aluminium, Zink etc.) bestehen.

Erlaubt ist der Gebrauch von

- Zangen und Schraubenziehern zum Öffnen der Behälter
- Messern zum Schneiden der Zeitzündschnüre und Sprengschnüre (Holzbrett als Schneidunterlage)
- Sprengkapselzangen zum Anwürgen der Sprengkapseln

Beim Hantieren mit Sprengmitteln dürfen stählerne Werkzeuge wie Hämmer und Brechisen nicht verwendet werden.
Transport

Transport von Sprengstoffen und Zündmitteln auf öffentlichen Verkehrswegen
Wenn Sprengstoffe und Zündmittel in Verkehrsmitteln, wie Eisenbahnen, Seilbahnen, Schrägaufzügen oder generell Motorfahrzeugen transportiert werden, beachten Sie die Bestimmungen der Sprengarbeitenverordnung sowie die Bestimmungen der ADR (Europäisches Übereinkommen über die internationale Beförderung gefährlicher Güter auf der Straße) und GGBG (Gefahrstoffbeförderungsgesetz).

Transport von Sprengstoffen und Zündmitteln vom Lager zur Sprengstelle
Transportieren Sie Sprengstoffe und Zündmittel entweder mit geeigneten Tragmitteln in ungeöffneter Lieferverpackung oder in verschlossenen Behältern aus nicht Funkenziehendem Material mit Schutzverkleidung (Schließkiste).
Trennen Sie außerdem Zündschnurzünder von Sprengstoffen und anderen Zündmitteln für den Transport.

Sprengstoffe und Zündmittel dürfen Sie auf keinen Fall in der Kleidung tragen, auch nicht in geringsten Mengen!
Grundsätzlich dürfen Sprengstoffe und Sprengschnüre einerseits und sprengkräftige Zündmittel andererseits nie von einer Person oder im selben Fahrzeug oder im selben Fördergefaß transportiert werden.

Ausnahme - Transport mit Schließkiste:
In einem Behälter aus nicht Funken ziehendem Material (Schließkiste) dürfen 5 kg Sprengstoff und 1 Rolle Sprengschnur sowie 50 Stück sprengkräftige Zünder in verschiedenen Abteilen dieses Behälters transportiert werden.

Lagerung, Ausgabe und Aufbewahrung

Lagerungsbestimmungen

Lagerung von brennbaren Sprengstoffen und Sprengschnüren oder Pulversprengstoffen
Bis 5 kg können diese in Räumen, aber unter sicharem Verschluss gelagert werden; in ihrer Nähe dürfen sich weder Feuerstellen noch feuergefährliche Gegenstände befinden.
über 5 bis 15 kg dürfen nur in Räumen gelagert werden, die folgende bauliche Anforderungen erfüllen:
- ebenerdige Lage,
- direkt ins Freie führende Türen mit Sicherheitsschloss,
- mit Stangen und Drahtgittern gesicherte Fenster,
- feuersichere Decke und
- keine Wohnräume unmittelbar daneben oder darüber.
In diesen Räumen dürfen sich weder Feuerstellen befinden noch feuergefährliche Gegenstände mitgelagert werden.

In diesen Räumen dürfen zusätzlich zu den Sprengstoffen und Sprengschnüren höchstens 100 sprengkräftige Zünder gelagert werden. Diese Zünder müssen in einem eigenen, versperrbaren Behälter untergebracht sein, der in möglichst großer Entfernung von den Sprengstoffen und Sprengschnüren steht.
Lagerung, Ausgabe und Aufbewahrung

Mehr als 15 kg müssen in eigenen Sprengmittelagern aufbewahrt werden.

Alle Sprengmittelager für eine Menge von mehr als 10 kg Sprengstoff müssen behördlich genehmigt sein.

Ausgabe von Sprengmitteln

Sprengstoffe und Zündmittel darf der Sprengbefugte erst unmittelbar vor Beginn der Ladung in der erforderlichen Menge aus dem Lager entnehmen. Beachten Sie, dass Sprengstoffe und sprengkräftige Zünder nicht zur selben Zeit ein und derselben Person ausgeflogen werden dürfen.

Sprengkraftige Zündmittel müssen nach der Ausgabe in geeigneten Behältern aus nicht Funken ziehendem Material aufbewahrt und transportiert werden.

Besondere Lagerungsbestimmungen
Eine Ausnahme bezüglich der auszuführenden Menge besteht dann, wenn die Sprengarbeiten an einem entlegenen oder unterirdischen Ort zu verrichten sind. In diesem besonderen Fall ist der voraussichtliche Tagesbedarf an Sprengstoffen und Zündmitteln auszufolgen werden.

Sprengstoffe und Zündmittel dürfen Sie niemals unbeaufsichtigt frei umherliegen lassen.

Das Abhandenkommen wie auch fehlende Bestände müssen Sie unverzüglich der nächsten Polizei oder Gendarmerie melden.

Verwahren Sie Sprengstoffe und Zündmittel bis zu ihrer Verwendung voneinander getrennt und sichern Sie sie vor Sprengstücken und unbefugtem Zugriff. Die Verwahrung hat in der Nähe der Sprengstelle in einem Tagesmagazin (einem versperrten, trockenen Raum) oder in Schießkisten (festen, dichten und versperrten Behältern) zu erfolgen.

Es ist verboten, andere Gegenstände als die Geräte und Hilfsmittel für die Sprengarbeit in Schießkisten oder Tagesmagazinen zu verwahren. Den Schlüssel zur Schießkiste oder zum Tagesmagazin hat der Sprengbefugte bei sich zu tragen.

In der Nähe der Schießkisten und Tagesmagazine dürfen sich kein Ofen, keine Feuerstellen und keine feuersäulenden Gegenstände befinden.

Schießkisten
Sie müssen bei feuchten Bodenverhältnissen entweder einen Doppelboden haben oder auf Holzunterlagen gestellt werden.

Tagesmagazine
Sie müssen von Aufenthaltsräumen und Arbeitsstellen so weit entfernt sein, dass im Falle eines Zündschlages keine Personen gefährdet sind.
Vernichtung

Vernichten Sie verdorbene oder unbrauchbare Sprengstoffe und Zündmittel fachgemäß. Auch nicht fristgerecht verwendete Sprengstoffe oder Zündmittel dürfen Sie nicht mehr verwenden.

Kennzeichen verdorbenen Sprengstoffes
- Pulverförmige Sprengstoffe sind verdorben, wenn sie feucht oder so hart sind, dass die Patronen mit der Hand nicht mehr weich gedrückt werden können.
- gelatinöse Sprengstoffe sind verdorben, wenn Sprengöl- ausschwitzung durch das Patronenpapier oder andere Zersetzungserscheinungen sichtbar werden.

Durch Kälteinwirkung hart gewordene gelatinöse, pulverförmige Sprengstoffe und Wettersprengstoffe sind nicht verdorben! Man darf sie trotzdem nicht verwenden, schneiden, reiben, brechen oder drücken. Vor einer Verwendung sind sie schonend aufzutauchen. Emulsionssprengstoffe sind bei tiefen Temperaturen sicherheitstechnisch unbedenklich (= nicht empfindlicher als bei normalen Temperaturen).

Woran man verdorbene Sprengstoffe erkennt.

Vernichtung

Kennzeichen unbrauchbarer Zündmittel
- Sprungkapsel:
  Verformt oder oxidiert; verschobenes oder verstopftes Innenhütlchen; strahlenförmige Zersetzungsstreifen um das Loch des Innenhütlchens
- Sprungzündgeräte:
  Verformt oder oxidiert; Boden der Schutzhülse beschädigt
- Elektrische Zünder:
  Verformt oder oxidiert; kein Stromdurchgang oder falscher Stromwiderstand
- Zeitzündschnur:
  Geknickt, brüchig oder feucht; chemisch verändert (eißig);
  Brennauer liegt nicht zwischen 110 bis 130 Sekunden pro Meter
- Zündschnurzünder:
  Feucht

Woran man unbrauchbare Zündmittel erkennt.
Bohren, Laden, Besetzen

Bohren

Der Durchmesser der Bohrlöcher für Patronen muss so groß sein, dass diese ohne Gewalt eingeführt werden können. Bei Pulversprengstoffen muss der Mindestdurchmesser 2 cm und die Mindesttiefe 20 cm betragen.

Untersuchen Sie Bohrlöcher und andere Laderaum vor dem Laden auf ihre Gängigkeit. Bohrlöcher und Laderaum sind zu reinigen und notigenfalls zu trocknen. (Stehet Pressluft zur Verfügung, sind sie auszublasen.)

Können Hindernisse nicht beseitigt werden, dürfen weitere Bohrlöcher nur in sicherem Abstand zu allenfalls bereits geladenen benachbarten Bohrlöchern angelegt werden.

Laden

Beim Fertigmachen der Ladung sowie beim Laden und Besetzen dürfen nur die unbedingt notwendigen Personen anwesend sein.

Auch zum Laden von Pulversprengstoffen dürfen Sie selbstverständlich nur Geräte und Hilfsmittel aus nicht Funken ziehendem Material verwenden.

Bringen Sie Patronen nicht mit Gewalt in die Laderräume! Wenn Sie dazu Ladestöcke verwenden, müssen diese aus Holz oder aus einem anderen nicht Funken ziehenden Material sein.

Verwenden Sie zum Einbringen von Patronen in Bohrlöcher in kluffigen Gestein auch Rohre oder Rinnen aus nicht Funken ziehendem Material.

Zum Vorklochen der Patronen zur Aufnahme der Sprengkapsel oder des Sprengzünders dürfen Sie nur einen geeigneten Dom aus Holz oder aus einem anderen nicht Funken ziehenden Material verwenden. Der Sprengzünder ist vollständig in den hergestellten Hohlraum zu führen. Bei Sprengkapseln darf das mit der Zündschnur verbundene Ende jedoch nur so weit eingeführt werden, dass die Zündschnur den Sprengstoff nicht berührt.

Verhindern Sie das Herausdrehen der Sprengkapsel oder das elektrischen Zünders aus der Schlagpatrone durch Anbinden der Patronen oder durch Schlaufen der Zünddrähte an der Patronen.

Werden verschiedene Sprengstoffe in ein und denselben Ladungsladesäule verwendet, muss zum Anfertigen der Schlagpatrone der brisanteste Sprengstoff eingesetzt werden.
Bohren, Laden, Besetzen

Schlagpatronen sind besonders vorsichtig und einzeln in das Bohrloch einzubringen. Es ist verboten, sie in Laderäume lediglich hinabzufallen zu lassen. Dasselbe gilt für Zündpatronen und für Schwerzulapaten.

Sonstige beim Laden stecken gebliebene Patronen muss der Sprengbefugte entweder durch eine aufgesetzte Schlagpatrone beseitigen oder vorsichtig mit der Räumkratze oder durch Ausblasen mit dem Blasrohr entfernen.

Tätigkeit nach dem Laden

Entfernen Sie nach dem Laden übrig gebliebene Sprengstoffe und Zündmittel sofort vom Sprengort und verwahren Sie diese in sicherer Entfernung (Schießkiste).

Besetzen

Zum Besetzen von Sprengladungen dürfen Sie grundsätzlich nur Materialien verwenden, die keine Funken ziehen. Es eignen sich also Materialien wie Lehm, Leichten, steinfreie Erde, Sand oder Split. Sprengladungen aus feuchtigkeitsunempfindlichen Sprengstoffen und Zündmitteln dürfen auch mit Wasser besetzt werden. Geben Sie einen Papierpropfen zwischen Sprengstoff und Besetzung, wenn
- loser Pulversprengstoff geladen oder
- die Schlagpatrone als letzte aufgebracht wird.

Wenden Sie beim Besetzen keine Gewalt an. Zum Besetzen dürfen nur Ladestücke aus nicht Funkenziehendem Material oder zugelassene Gerätetypen verwendet werden.

Besonderheiten bei aufziehendem/niedergehendem Gewitter

Bei aufziehendem Gewitter darf bei Sprengung mit elektrischer Zündung ober und knapp unter Tag weDer geladen noch besetzt werden. Zündfertige Ladungen sind so rasch wie möglich abzuladen.
Bohren, Laden, Besetzen

Bei schlechter Sicht
Bei Nebel oder Nacht darf auf keinen Fall gesprengt werden.

Zünden und Sprengsignale

Zünden einer unterbrochenen Ladung
Wurden in einen Laderaum bissante Sprengstoffe in Teilladungen eingebracht und wurde der Raum zwischen den Teilladungen nicht mit Besatzmaterial ausgefüllt (unterbrochene Ladung), ist vorzugsweise mit Sprengschnur zu zünden, oder es muss jede Teilladung mit Sprengzündern gezündet werden.

Zündung bei geteilter Ladung
Wurde der Raum zwischen den Teilladungen mit Besatzmaterial ausgefüllt (geleitete Ladung) und soll mit Verzögerung gezündet werden, so muss der Zwischenbesatz ausreichend lang sein, um Zündüberschläge zu vermeiden.

Bei elektrischer Zündung ohne Sprengschnur ist jede Teilladung mit einer Schießpatrone zu versehen. Es dürfen nur elektrische Moment- oder Millisekundenzünder verwendet werden.

Bei Zündung mit Sprengschnur muss diese an jeder Teilladung anliegen.

Werden Sprengverzögerer verwendet, sind diese im Zwischenbesatz anzuordnen. Sie müssen außerdem vor Beschädigung geschützt sein, wie durch Überschubhülsen, die mit der Sprengschnur fest verbunden sind.

Besonderheiten bei Zeitzündschnur-Zündung

Die Zündung mit Zeitzündschnur sollte auf Einzel-Einsignale beschränkt bleiben.

Zeitzündschnüre müssen mindestens 1 m lang sein und mindestens 20 cm aus den Bohrlöchern ragen. Werden
Zünden und Sprengsignale

Zündschnurzünder verwendet, darf eine Person höchstens 10 Zündungen vornehmen und dies nur dann, wenn die Zündstellen nahe beieinander liegen und leicht erreichbar sind.

Ist dies nicht der Fall, darf eine Person höchstens 4 Zündungen vornehmen. Wird als Zündschnurzünder eine gekerbte Zeitzündschnur (Kerbschnur) verwendet, so darf sie höchstens halb so lang sein wie die kürzeste der anzuzündenden Zeitzündschnüre.

Zündung mit Sprengschnur und Sprengverzögerer
Bei Zündung mit Sprengschnur dürfen sich in den Sprengladungen keine Sprengkapseln befinden. Bei Bohrlöch- und Lassensprengungen muss die Sprengschnur bis zum Bohrlöchertiefen oder Lassen tiefstehend geführt werden.

Sprengverzögerer sind mit Sprengschnüren zu zünden. Bei Verwendung außerhalb von Laderäumen müssen sie in der Leitsprengschnur (das ist die unmittelbar zur Detonation gebrachte Sprengschnur) so angeordnet werden, dass die Wirkungsweise der Verzögerer nicht beeinträchtigt wird.

Verzögerer müssen außerdem so verlegt werden, dass sie unbeabsichtigt weder beschädigt noch zur Detonation gebracht werden können (Sicherheitsdatenblatt und mitgeliefertes Sprengstoffmerkblatt beachten). Sie sollen diese Verzögerer zur Minimierung des auftretenden Schalles mit Sand oder Bohrmehl abdecken.

Sprengsignale

Bei Sprengungen über Tag sind drei Sprengsignale zu geben, deren Bedeutung durch Anschlag bekannt zu geben ist:

**Erstes Sprengsignal**
- 1 langer Ton
- Deckung aufsuchen
- Straubereich räumen

**Zweites Sprengsignal**
- 2 kurze Töne
- Zünden

**Drittes Sprengsignal**
- 3 kurze Töne
- Sprengung beendet

Sprengablauf
Das erste Sprengsignal ist zu geben, wenn
- das Laden und Besetzen beendet ist und alle Schüsse zum Zünden vorbereitet sind (Zünderkette geschlossen, Zündleitung geprüft und mit der Zünderkette verbunden; Sprengschnur verlegt, Sprengverzögerer eingebaut, Sprengkapsel oder elektrischer Sprengzünder befestigt);
- die vorgeschriebene Sprengzeit eingehalten wird;
- bei Gewitter die Sprengladungen nicht mehr abgetan werden können.
Zünden und Sprengsignale

Das zweite Sprengsignal ist zu geben, wenn
- sich mit Ausnahme der zum Anzünden notwendigen Personen keine weiteren Personen im Streubereich oder außerhalb der Deckung befinden;
- bei elektrischer Zündung die Anlage auf ihren Gesamtwiderstand geprüft und in Ordnung befunden wurde.

Bei Zündung mit Zeitzündschnur haben sich nach dem Anzünden alle daran Beteiligten unverzüglich in Deckung zu begeben oder den Streubereich zu verlassen.

Zünden und Sprengsignale

Das dritte Sprengsignal ist zu geben
- bei Sprengung mit Zeitzünder, wenn alle Schüsse einwandfrei gezählt wurden;
- bei Zündung mit elektrischen Moment- oder Zeitzündern und bei Sprengung mit Sprengschnur sowie Shock-Star-Zündung, nachdem der letzte Schuss gekommen ist;
- bei allen übrigen Sprengungen 15 Minuten nach dem Kommen des letzten Schusses;
- wenn ein Schuss versagt, ausgeblasen oder ausgekocht hat oder Zweifel darüber bestehen, ob alle Schüsse ordnungsgemäß gekommen sind, sobald der Sprengbefugte auf Grund einer Besichtigung der Ansicht ist, dass keine Gefahr mehr besteht.

Ein solche Besichtigung darf frühestens 15 Minuten nach dem Zeitpunkt vorgenommen werden, an dem der letzte Schuss bei ordnungsgemäß Zündung hätte kommen müssen. Der Ablauf der Wartezeiten ist vom Sprengbefugten mit der Uhr festzustellen.

Zwischen dem zweiten und dritten Sprengsignal darf außer dem Sprengbefugten niemand die Deckung verlassen oder den Streubereich betreten.
Versagerbeseitigung

Richtiges Verhalten bei Versagern

Bei Schichtbetrieb obliegt die Untersuchung und Sicherung des Sprengorts der Belegschaft der abgehenden Schicht. Kann sie die damit verbundenen Arbeiten innerhalb ihrer Schicht nicht mehr oder nicht mehr ganz verrichten, so muss der Sprengbefugte der abgehenden Schicht seinen Ablöser direkt am Sprengort über den Stand der Arbeiten informieren.

Die Beseitigung von Versagern durch daneben gesetzte Hilfschüsse ist verboten! Das Nach- oder Tieferbohren von Bohrlöchern sowie stehen gebliebenen Bohrlöchern und Lassen ist verboten (Lebensgefahr durch Sprengstoff- oder Zündmittelrasten)

Versager in Bohrlöchern oder Lassen können Sie auch dadurch beseitigen, wenn Sie die Vorgabe durch auf- oder umgelegte Sprengladungen allmählich beseitigen, bis die Ladung des Versagers mit zur Detonation kommt. In diesem Fall ist ein vergrößerter Streuereich festzulegen.

Möglichkeiten der Besatzerntfernung
Bei voll besetzten Laderäumen mit brisanten Sprengstoffen 

Wichtig
Wie man den Besatz richtig entfernt.

Bei voll besetzten Bohrlöchern mit Pulversprengstoffen

Ganzen Besatz einschließlich Papierpropfen mit Räumkratz aus nicht Funken ziehendem Material entfernen, neues Zündmittel mit etwas Sprengstoff einführen, wieder besetzen und abtun.

Das Ausblasen des Besatzes mit Pressluft ist erlaubt, wenn durch den Papierpropfen das Ausblasen von Pulversprengstoff sicher verhindert wird.
Gesundheitsvorsorge

1. Bei Sprengarbeiten besteht Rauchverbot und Alkoholverbot.
2. Sprengöl kann durch die Haut aufgenommen werden. Maßnahmen dagegen sind:
   - Schutzhandschuhe verwenden;
   - mit beschmutzten Händen nicht essen, rauchen oder trinken.
3. Sprengstoffdämpfe nicht einatmen. Auf erhöhten Standplätzen zusätzlich Absicherung berücksichtigen. (Durch Sprengstoffdämpfe besteht die Gefahr der Bewusstlosigkeit.)

Ausrüstung komplett?

- Schutzhelm, Schutzhandschuhe, Gehörschutz, Sicherheitsschuhe
- Tragbehälter mit Schloss (Schießkiste)
- Kugelschreiber, Notizblock
- Kreide oder Farbe
- Sprengbuch
- Meterstab
- Taschenmesser
- Holzdorn
- Isolierband (Bindfaden, Isolierdraht)
- Sprengkapselzange (Amütsgeapparat)
- Zündschnurzünder (Streichhölzer)
- Ladestock
- Signalgerte (Funkgerät, rote Flaggen, Horn)
- Warnkleidung
- Räumkratze
- Zündkornsprüfer
- Zündmaschinenprüfgerät
- Uhr
- Markierungsspray

1. Vorwort
Diese SGU-Broschüre ist eine Hilfestellung für unsere neuen Mitarbeiter, um bei der STRABAG AG sicher, gesund und umweltbewusst zu arbeiten.
Wir nehmen Sicherheit und Gesundheit in unserem Unternehmen sehr ernst und setzen uns nachdrücklich für den Schutz der Umwelt ein. Aus diesem Grund wurden von den Geschäftsführern in der Erklärung zur SGU-Politik ausdrücklich die folgenden Grundsätze formuliert:

1. Verhindern aller persönlichen Schäden
Sicher arbeiten bedeutet, dass man Gefahren erkennt und man sich selbst sowie seine Kollegen davor schützt. Lassen Sie sich darüber stets von Ihren Vorgesetzten, erfahrenen Kollegen und Auftraggebern informieren.
Ein hohes Sicherheitsbewusstsein wird von allen erwartet und wird auch gefördert. Um Unfälle zu verhindern, sind bei allen Arbeiten nur die sichersten Verfahren mit der entsprechenden Sorgfalt anzuwenden.

2. Verhindern von Gesundheitsschäden
Um Gesundheitsschäden vorzubeugen, sind Ordnung, Sauberkeit und Hygiene von außerordentlicher Bedeutung. Alle Baustellen sind so eingerichtet, dass gefährliche Bedingungen dort stets eingehalten werden. Benutzen Sie grundsätzlich nur die sanitären Einrichtungen.

3. Verhinder von Schäden an der Umwelt
Ein Anliegen unseres Unternehmens ist es, umweltbewusst zu arbeiten. Die Ablaufvermeidung spielt dabei eine wichtige Rolle. Alle Abfälle gehören in die dafür bereitgestellten Behälter und nicht daneben.

SGU - Eine Sache, die jeden angeht
Wir wünschen Ihnen eine sichere, gesunde und erfolgreiche Zukunft bei der STRABAG AG
Die Unternehmensleitung
2 Allgemeine Sicherheitsvorschriften

Das Tragen von Schutzhelmen und Schutzausrüstung ist Pflicht. Sofern ein Risiko für Kopfverletzungen besteht, etwa durch herunterfallende Geräte, Materialien oder durch Anstoßen, ist das Tragen eines Schutzhelms ebenfalls Pflicht.

Je nach Art der Arbeit ist der Gebrauch persönlicher Schutzausrüstung vorgeschrieben und verpflichtend:

- Tragen von Schutzbrillen, um die Augen vor unherfleckenenden Gegenständen zu schützen
- Tragen von Handschuhen, um Verletzungen an den Händen zu vermeiden (nicht aber an Kreissägen)
- Tragen von Ohrenschutzern bei starkem Lärm

Halten Sie Ordnung und Sauberkeit auf der Baustelle und in den Container. Halten Sie Durchgänge, Verkehrswege und Zufahrten frei.

Lassen Sie NIEMALS eine Baugrube oder einen Kanalgraben zurück, ohne eine gut erkennbare Abgrenzung und Beleuchtung anzubringen. Alle Öffnungen auf der Baustelle müssen ordnungsgemäß abgedeckt werden.

Allgemeine Schutzmaßnahmen gegen den Absturz von hohen Arbeitsplätzen wie Gerüste, Leitern, Fassaden, Treppenfeldern sind:

- unmittelbar dort anzubringen, wo dies erforderlich ist
- NIE ohne Erlaubnis zu entfernen.

Elektrische Defekte an Geräten, Maschinen oder Verlängerungskabeln müssen unmittelbar dem direkten Vorgesetzten gemeldet werden. Der weitere Gebrauch ist nicht zulässig.

Verwenden Sie nur Leitern, die sich in ordnungsgemäßer Zustand befinden. Es werden nur Leitern in ausreichender Länge benutzt. Diese müssen stets oben befestigt werden.

Qualität heißt MITDENKEN!

Sauerstoff- und Gasflaschen sind immer aufrecht zu stellen und festzubinden. Defekte an der Ausrüstung von Brennern oder Verbindungsvorrichtungen sind sofort dem Vorgesetzten zu melden.

Benutzen Sie auf fahrenden Baumaschinen nur die Sitzplätze, die dafür vorgesehen sind. Halten Sie an Gabelstapler / Ladem während der Fahrt die Hebevorrichtungen immer so dicht wie möglich am Boden. Parken sie auch in dieser Stellung.

Maschinen dürfen ausschließlich von dazu beauftragten, beauftragten und angeleiteten Personen bedient werden.

Auf den Baustellen der STRABAG gilt absolutes Alkoholverbot.

Vermelden Sie jede Handlung, die entweder Sie oder Ihre Kollegen einer Gefahr aussetzt.

Besetzen Sie alle gefährlichen Situationen unverzüglich oder melden Sie diese Ihrem Vorgesetzten!

Mit persönlicher Schutzausrüstung (PSA) können Sie Verletzungen an Kopf, Händen, Füßen und Augen vorbeugen.

Gute Arbeitshandschuhe schützen vor
- Stich- und Schnittwunden
- Hautkrankheiten
3 Persönliche Schutzausrüstung (PSA)

Der Betrieb stellt Ihnen folgende Ausrüstung zur Verfügung:

- Sicherheitsschuhe
- Schutzhelm
- Handschuhe

Diese Ausrüstung soll Sie vor den häufigsten Risiken auf einer Baustelle schützen. Tragen Sie diese dann auch! Sie sind dazu verpflichtet.

Daneben sollten für spezielle Arbeiten zusätzlich passende persönliche Arbeitsschutzmittel getragen werden z. B. Sicherheitsbrille und Gehörschutz.

Alle erforderlichen Arbeitsschutzmittel müssen stets vollständig auf der Baustelle vorhanden sein.

4 Gebots- und Warnhinweise

Gebotsbilder können zum Beispiel angeben, welche persönliche Schutzausrüstung verpflichtend zu tragen ist.

Runde Form – weiß auf blauem Hintergrund

Verbotsbilder weisen auf Handlungen hin, die verboten sind.

Runde Form – schwarz auf weißem Hintergrund mit rotem Rand/Balken

Nicht rauchen
Zutritt verboten

Warnschilder weisen Sie auf eine mögliche Gefahr hin.

Dreieck – schwarz auf gelbem Hintergrund

Gefahr vor elektrischer Spannung
Gefahr durch Staub
Warnung vor infektiösem Leiden
5 Ordnung, Sauberkeit und Hygiene
Ordnung und Sauberkeit sind die Visitenkarte jeder Bauimmaterie.
Zum Ende der Arbeiten, auch bei der Beendigung des Arbeitstages, sollte darauf geachtet werden, dass die Umgebung aufgeräumt ist.
Treppen, die Umgebung von Leitern, Fluchtwegen, Zufahrten sowie der Zugang für Rettungsfahrzeuge müssen stets freigehalten werden.
Halten Sie die Unterkünfte und sanitären Anlagen stets sauber und benutzen Sie die vorgesehenen Abfallbehälter!

6 Gefahrensymbole
Gefahrensymbole sind notwendig, um auf mögliche Risiken gefährlicher Produkte hinzuweisen. Sie befinden sich auf den Etiketten der entsprechenden Produkte.
Schwarz auf orangem Hintergrund

7 Maschinen und Geräte
Achten Sie darauf, dass Öffnungen auf der Baustelle ordentlich gesichert sind.

NEIN

Benutzen Sie Leitern mit ausreichender Länge auf festem Boden

NEIN

Dies gilt auch für den Ein- und Ausstieg in Gräben.

JA
Bei Erdarbeiten besteht die Gefahr, dass Wände einstürzen, deshalb Grubenverbau bis über die Oberfläche führen.

Benutzen Sie die vorgesehenen Tritte, springen Sie nicht ab.

Auf Straßen immer für richtige Absperrung sorgen.

Halten Sie mit Geräten Abstand von Geländekanten.

Beim Rückwärtsefahren auf toten Winkel achten, Gefahr für Mitarbeiter.

Ordnung und Sauberkeit, für IHRE und MEINE Sicherheit!
Ein Handwerker arbeitet nur mit richtigem Material, das keine Mängel aufweist und benutzt nur passende Geräte.

Reparaturen an elektrischen Geräten, Kabeln und Maschinen dürfen nur von Elektrofachkräften durchgeführt werden.

Behalten Sie das Material mit dem nötigen Respekt und lassen Sie nichts herumliegen.

Gebrauchen Sie stets geprüftes Material! Überprüfen Sie ihren Materialbestand vor Gebrauch:

- Sind Sicherheitsaufkleber angebracht?
- Ist das Prüfdatum noch nicht überschritten?
- Nach Gebrauch immer noch in gutem Zustand?
- Haben Sie Erfahrung mit diesem Material?

9 Brand
Vorbeugen ist besser als löschen!
Was ist im Brandfall zu tun?
Bewahren Sie unter allen Umständen die Ruhe - keine Panik!
ALARM GEBEN
- benachrichtigen Sie unverzüglich den Vorgesetzten, die Feuerwehr und Ihre Kollegen
LÖSCHEN
- nehmen Sie den nächsten Feuerlöscher und versuchen Sie den Brand zu löschen
- geben Sie kein Risiko ein
Verlassen Sie das Gebäude / die Baustelle, sobald Sie die Alarmsirenen hören
- begeben Sie sich sofort zum Sammelplatz, wo die Verantwortlichen kontrollieren, ob alle anwesend sind
Feuerlöscher
Das meist gebrauchte Brandlöschgerät auf STRABAG-Projekten ist der Feuerlöscher Typ ABC 6 kg. Wie Sie ihn zu bedienen haben, steht auf dem Etikett am Löschgerät:
1. Sicherheitsstift herausziehen
2. Hebel vollständig hinein drücken
3. in Flammenfuß richten und den Spritzhebel (Sprühventil) eindrücken
Der ideale Abstand vom Feuerlöscher zum Brand beträgt 3 bis 4 m.
Gebrauchte und beschädigte Geräte müssen direkt ausgetauscht werden.
10 Schlusswort

Dies war die erste Information über sichere, gesunde und umweltbewusste Arbeiten bei der STRABAG.

Nun liegt es an Ihnen, diese Richtlinien sorgfältig zu befolgen.

Haben Sie noch Fragen? Sie können sich stets an Ihren Vorgesetzten oder die Sicherheitsfachkraft wenden!

Viel Erfolg!

Der Gebrauch von Feuerlösachern:

Falsch

Richtig

1. Nur in Richtung aufgeroter und brennenden.

2. Fensteröffnungen vor Brandeinstreuung.

3. Lõschlöscher gleichzeitig einsetzen, nicht nacheinander.

4. Vorsicht vor Wiederentflammung.

5. Gebrauchte Flaschen nicht wieder zuzuschließen, Sie müssen ausreichend gekühlt werden.
Strabag Betriebsanweisungen

1. Geräte zur Herstellung, Transport und Verteilung von Beton
   1.1. Autobetonpumpen mit Verteilermast

2. Hebezeuge
   2.1. Krane
   2.2. Mobiikran / Autokran
   2.3. LKW-Ladekran
   2.4. Arbeitskorb / sonst. Personenaufnahmemittel (PAM)
   2.5. Hubstapler

3. Geräte zur Erdbewegung und Bodenverdichtung
   3.1. Seilbagger
   3.2. Hydraulikbagger
      3.2.1. Schnellwechsleinrichtungen
      3.2.2. Heben von Einzellastran mit Bagger und Baggerlader
   3.3. Baggerlader
   3.4. Kleinlader
   3.5. Lade – Planiergeräte
   3.6. Grader
   3.7. Muldenkipper
   3.8. Kleindumper
   3.9. Waizen
   3.10. Radlader

4. Bohrgeräte
   4.1. Raupenbohrgerät

5. Straßenbaugeräte
   5.1. Straßenfertiger

6. Geräte für Tunnel – und Stollenbau
   6.1. Bohrwagen

7. Sonstige Geräte und Einrichtungen
   7.1. Bolzensatzgeräte: ÖNORM Z 1541
   7.2. Geräte für autogener Schweißen und Schneiden: Plakat AUVA
   7.3. Lagerung und Verwendung von Flüssiggasflaschen
   7.4. Sonstige selbstfahrende Arbeitsmittel mit Fahrersitz
   7.5. Handgeführte selbstfahrende Arbeitsmittel
   7.6. Elektrisches Handwerkzeug

Die Betriebsanweisungen sind Bestandteil der Sicherheitsdatenbank im Lotus Notes!
HINWEIS FÜR DEN AUFSEITSPFlichtigen BAUKRFTRFORDER

Für die Bedienung des übernommenen Gerätes sind nur unterwiesene und bereits mit dem Gerät vertraute Arbeiternehmer heranzuziehen. Welts ist eine gerätebezogene Fahrbevollmachtung zu erteilen.

Vor der Verwendung eines für den Benutzer neuen Gerätes hat dieser die BetriebSANleitung des Herstellers zu lesen oder es ist zumindest eine Unterweisung durch einen bereits mit dem Gerät vertrauten Mitarbeiter zu veranlassen. Besonderes Augenmerk auf fremdsprachige Arbeitnehmer.

Achtung: Kennzeichen und Führerscheinfpllicht auf öffentlichen Straßen oder Plätzen!

SICHERHEITSSCHRIFFNÄMEN UND VERHALTENSREGELN

Kein offenes Feuer, nicht rauchen, sich vom Standort des nächsten Feuerlöscherch überzeugen.

Für die Zeit der Abwesenheit des Baustellenführungspersonals von der Baustelle wird

Herr ................................................

als geeigneter Arbeitnehmer gemäß §4 BauV bestellt.

Er besitzt die für die gewissenhafte Durchführung der auszuführenden Arbeiten erforderlichen praktischen Kenntnisse. Gemäß BauV §4 bestätigt er, von der obengenannten Aufsichtsperson über die bei den auszuführenden Arbeiten zum Schutz der Arbeitnehmer notwendigen Maßnahmen unterwiesen worden zu sein, sowie dieser Bestellung auch zuzustimmen.

Ort: Unterschrift Bauleiter / Polier / VA:

Datum: Unterschrift geeigneter Arbeitnehmer:

Erläuterung:

**BauV §4 (Bauarbeiter-Schutzverordnung):**
Wenn die Aufsichtsperson auf der Baustelle nicht ständig anwesend ist, ist ein auf der Baustelle beschäftigter geeigneter Arbeitnehmer zu bestellen, der in Abwesenheit der Aufsichtsperson auf die Durchführung und Einhaltung der zum Schutz der Arbeitnehmer notwendigen Maßnahmen zu achten hat. Es darf nur ein Arbeitnehmer bestellt werden, der

1. die Gewähr für eine gewissenhafte Durchführung der übertragenen Aufgaben bietet,
2. die für die auszuführenden Arbeiten erforderlichen praktischen Kenntnisse besitzt,
3. von der Aufsichtsperson über die bei den auszuführenden Arbeiten zum Schutz der Arbeitnehmer notwendigen Maßnahmen nachweislich besonders unterwiesen worden ist und
4. seiner Bestellung nachweislich zugestimmt hat.

1. Die nachstehend angeführten Personen (Besucher) wurden durch den Vertreter (Führer) der Besuchergruppe über die Gefährdungen im angeführten Bereich/Baustelle fachkundig informiert und haben diese Information auch verstanden. Der Vertreter der Besuchergruppe übernimmt die Verantwortung für die sichere Führung der Besuchergruppe auf der Baustelle/Bereich.

3. Das Betreten der Baustelle/Bereiche durch die Besuchergruppe erfolgt auf deren eigene Gefahr. Die STRABAG AG, ihre Mitarbeiter und Subunternehmern haften für Schäden der Besuchergruppe nur bei Vorsatz oder grober Fahrlässigkeit.

5. Den Anweisungen des Baustellenpersonals ist Folge zu leisten.

6. Der Vertreter der Besuchergruppe bestätigt mit Wirkung für sich und die übrigen Besucher die Einhaltung der obigen Bedingungen.

Die detaillierte Auswertung von Arbeitsunfällen erfolgt durch die jeweils für den Bereich zuständige Sicherheitsfachkraft, die eine Kopie der Unfallmeldung und diese Zusammenfassung zur statistischen Auswertung der Arbeitsunfälle an den für die Erstellung der Direktionsunfallstatistik Beauftragten weiterleitet. Der für die Erstellung der Direktionsunfallstatistik verantwortlich Beauftragte leitet diese nach Erfassung aller Arbeitsunfälle eines Wirtschaftsjahres am Beginn des Folgejahres bzw. auf Aufforderung an den Konzernbeauftragten für Arbeitnehmerschutz weiter (⇒ Konzernstatistik).

Die hier einzutragenden Kennziffern sind dem Formular „FB 3.5-STO-10 - Unfallursache – Schlüsselnummern“ zu entnehmen! Nur eine Schlüsselnummer je Kategorie eintragen !!!

Unterlage für spätere Arbeiten gemäß §8, BauKG

Bauvorhaben

Inhaltsverzeichnis:

- Unterlage detailliert (Seiten)
- Beilagen (Fotodokumentation) (Seiten)
- Statik ⇒
- Einbautenpläne ⇒
- Installationspläne – Wasser, Gas, Elektro, Fernwärme etc. ⇒

Zur Kenntnis genommen:

Bauherr  Baustelle  Baustellenkoordinator
An

Wien, am

Betreff: Bauvorhaben XXXX
Thema: Bauarbeitenkoordinationsgesetz (BauKG)

Sehr geehrte Damen und Herren!

Aus Auftragnehmer im Zuge der Erstellung des o.a. Bauvorhabens verweisen wir auf die
Anwendbarkeit des BauKG, aufgrund

- Überschreiten der Schwellenwerte (Personentage) lt. §6(1)
- Beschäftigung mehrerer Auftragnehmer lt. §3(1)
- Arbeiten mit besonderen Gefahren lt. §7(2).

Im Sinne des BauKG hat der Bauherr dafür zu sorgen, dass die beauftragten Arbeitgeber die
gemäß BauKG geltenden Bestimmungen zur Verbesserung der Sicherheit und des
Gesundheitsschutzes einhalten.

Als betroffener Arbeitgeber ersuchen wir daher um Übermittlung nachfolgender Unterlagen:

- Vorankündigung gemäß § 6
- Sicherheits- und Gesundheitsschutzplan gemäß § 7
- Unterlage für spätere Arbeiten gemäß § 8

Weiters ersuchen wir um Bekanntgabe des

- Namen und Adresse des Planungs koordinators
- Namen und Adresse des Baustellenkoordinators.

Mit freundlichen Grüßen

Für die Baustelle

Einleitung

SCC (Sicherheits Certifikat Contraktoren) ist ein Managementsystem auf dem Gebiet von Sicherheit, Gesundheits- und Umweltschutz.

Um das SCC-Zertifikat zu erlangen, sind mehrere vorgeschriebene Kriterien zu erfüllen. Eines davon verlangt, dass ein Unternehmen, welches als Subunternehmer auf den unter SCC-Auflagen laufenden Baustellen tätig ist, ebenfalls die entsprechenden Erfordernisse erfüllt.

Als Nachweis hiefür bieten sich zwei Möglichkeiten:

Variante 1: Das Unternehmen weist nach, dass es das SCC-Zertifikat (oder gleichwertiges) erhalten hat.

Variante 2: Das Unternehmen wird durch den Auftraggeber auf Basis der SCC-Checkliste (Dokument CH 3.5-STO-07) beurteilt. Grundlage hiefür ist die Beantwortung des vorliegenden Fragebogens.

In jedem Fall kann sich der Auftraggeber des Subunternehmers durch Einblicknahme in Nachweise, durch Vorliegenlassen von Unterlagen und/oder durch Kontrolle auf der Baustelle von der Erfüllung der geforderten Kriterien überzeugen.

Im Falle einer Beauftragung des Unternehmens sind die im Anhang zum Fragebogen geforderten Unterlagen vor Beginn der Arbeiten dem Bauleiter des Auftraggebers schriftlich zu übergeben.

Erläuterung zum Ausfüllen des Fragebogens:

Wenn das Unternehmen seinerseits ein SCC-Zertifikat erhalten hat, ist eine Kopie desselben zu übermitteln (vgl. Variante 1 der Einleitung). Der unausgefüllte Fragebogen ist beizulegen.

Außer: das Unternehmen unterliegt nicht dem Geltungsbereich des Arbeitnehmerinnenschutzgesetzes ASchG (Frage 1.1)! In diesem Fall nur Punkte 1.1, 8. und 9. ausfüllen!

Zutreffende Kästchen sind anzukreuzen: im Abschnitt 1 sind zusätzliche Angaben gefordert.

**Anhang zum Fragebogen**

Im Falle einer Beauftragung ist auf Anfrage vorzulegen:

- Name der Aufsichtsperson
- Name des Stellvertreters der Aufsichtsperson
- Nachweise betreffend Abschnitt 1 des vorliegenden Fragebogens
- Auflistung der Namen der auf der Baustelle eingesetzten Führungskräfte und operativen Mitarbeiter.
  
  Auf dieser Auflistung sind zusätzliche Angaben erforderlich betreffend
  - fachliche Qualifikation
  - besondere Qualifikationen, falls zutreffend (z. B. Staplerfahrer, Ersthelfer, etc.)
  - Hinweis auf Deutsch-Kenntnis, falls erforderlich (zumindest 1 AN je Partie)
  - Formblatt mit Inhalt und Datum der letzten Unterweisung durch das Unternehmen, sowie
    Namen und Unterschriften der unterwiesenen Mitarbeiter
  - Evaluierung

Bei Veränderungen sind die Angaben zu aktualisieren.

---------------------------------------------
Ort, Datum                                      Für das Unternehmen
Einleitung

SCC (Sicherheits Certifikat Contraktoren) ist ein Managementsystem auf dem Gebiet von Sicherheit, Gesundheits- und Umweltschutz.

Um das SCC-Zertifikat zu erlangen, sind mehrere vorgegebene Kriterien zu erfüllen. Eines davon verlangt, dass ein Unternehmen, welches als Personaldienstleister für unter SCC-Auflagen laufende Baustellen tätig ist, Erfordernisse, die der SCP-Checkliste entsprechen, erfüllt. (SCP bedeutet „Sicherheits Certifikat Personaldienstleistungen“, ist Teil der Unterlagen des Sektorkomitees SCC Austria.

Als Nachweis hiefür bieten sich zwei Möglichkeiten:

Variante 1: Das Unternehmen weist nach, dass es das SCP-Zertifikat erhalten hat.

Variante 2: Das Unternehmen wird durch den Auftraggeber auf Basis der SCP-Checkliste (Dokument CH 3.5-STO-08) beurteilt. Grundlage hiefür ist die Beantwortung des vorliegenden Fragebogens.

In jedem Fall kann sich der Auftraggeber des Personaldienstleisters durch Einblickeinahme in Nachweise, durch Vorliegenlassen von Unterlagen und/oder durch Kontrolle auf der Baustelle von der Erfüllung der geforderten Kriterien überzeugen.

Im Falle einer Beauftragung des Unternehmens sind die im Anhang zum Fragebogen geforderten Unterlagen vor Beginn der Arbeiten dem Bauleiter des Auftraggebers schriftlich zu übergeben.

Erläuterung zum Ausfüllen des Fragebogens

Wenn das Unternehmen ein SCP-Zertifikat erhalten hat, ist eine Kopie desselben zu übermitteln (vgl. Variante 1 der Einleitung). Der unausgefüllte Fragebogen ist beizulegen.

Erfolgt die Beurteilung des Unternehmens durch den Auftraggeber (vgl. Variante 2 der Einleitung), ist die Erfüllung sämtlicher Fragen dieses Fragebogens mit „Ja“ Voraussetzung für eine Beauftragung als Personaldienstleister.

Sind zum Zeitpunkt der Beantwortung der Fragen noch nicht alle Forderungen erfüllt, hat das Unternehmen unverzüglich nachweisbare Maßnahmen zu ergreifen, welche die Erfüllung in Zukunft sicherstellen und darf die betreffenden Fragen positiv beantworten.

Außer: das Unternehmen unterliegt nicht dem Geltungsbereich des ArbeitnehmerInnenschutzgesetzes ASchG (Frage 1.1)! In diesem Fall nur Punkt 1.1 ausfüllen!

Zutreffende Kästchen sind anzukreuzen; im Abschnitt 1 sind zusätzliche Angaben gefordert.
Unternehmen:

(Name, Anschrift, Tel., e-mail, etc.)

Branche:
Name des Firmenleiters/
der Firmenleiterin:

Anhang zum Fragebogen

Im Falle einer Beauftragung ist auf Anfrage vorzulegen:

- Nachweise betreffend Abschnitt 1 des vorliegenden Fragebogens

- Auflistung der Namen der auf der Baustelle eingesetzten Führungskräfte und operativen Mitarbeiter.

Auf dieser Auflistung sind zusätzliche Angaben erforderlich betreffend

-- fachliche Qualifikation
-- besondere Qualifikationen, falls zutreffend (z. B. Staplerfahrer, Ersthelfer, etc.)
-- Hinweis auf Deutsch-Kenntnis, falls erforderlich (zumindest 1 AN je Partie)

- Formblatt mit Inhalt und Datum der letzten Unterweisung durch das Unternehmen, sowie Namen und Unterschriften der unterwiesenen Mitarbeiter

Bei Veränderungen sind die Angaben zu aktualisieren.

Arbeitsvorgänge

**Aushubarbeiten**

**Gefahren:** Verschütten * Absturz * Stürzen / fallen

**PSA:** Sicherheitsschuhe/-stiefel

**Unterlagen:** AUVA M 223 * BauV 6. Abschnitt * Baumappe C1-C6 * Baumappe 2002 D1 Böschungen * Baumappe 2002 D4 Baugrubenverbau * Baumappe 2002 D2 Grabenverbau

**Böschungen**

**Maßnahmen:** Die Böschungsneigung fachgerecht wählen (Bodenart, Auflasten, Erschütterungen, Grundwasser etc.). * Ohne Nachweis Regelböschung möglich; 45° für Stichböden; 60° für Hackböden; 80° für Schrämmböden; 90° für Sprengböden. * Bei Abweichung rechnerischer Nachweis erforderlich (aufstehend und Kontrolle ob der Boden dem Nachweis entspricht). * Ggf. Maßnahmen gegen Witterungseinflüsse wie Zementmörtelspritzer, Spritzbeton, Folienabdeckung. * Bei Gräben und Baugruben bis 1.25 m Tiefe können die Wände senkrecht angelegt werden, wenn der Boden standfest ist (Auflasten beachten).

**Gefahren:** Verschütten * Rollen/Gleiten/Abrutschen

**Prüfungen:** Regelmäßige Überprüfung

**Unterlagen:** Baumappe C4 * AUVA M 223 * BauV 6. Abschnitt * Baumappe 2002 D1 Böschungen

**Transport/Laden händisch**

**Maßnahmen:** Ladung ausreichend sichern (Verspannen, Verkeilen, Versperren). * Transportfahrzeug max. Breite/Höhe 2,5 m/4 m, sonst Ausnahmegenehmigung. * Sichere Auffahrtsrampe verwenden, geeignete Hebehilfen einsetzen.

**Sonstiges:** Auf physische Leistungsfähigkeit ist zu achten.

**Gefahren:** Quetschen * Kippen/Herabfallen * Überlastung
PSA: Sicherheitsschuhe/-stiefel * Ggf. Schutzhandschuhe

Fachkunde: Für Jugendliche ist das Manipulieren von schweren Lasten verboten

Unterlagen: Baumappe D4 * Baumappe 2002 D23 Transport / Ladungssicherung

Transport/Laden maschinell

BETRIEBSANWEISUNG

SEILBAGGER

Hinweis für den aufsichtspflichtigen Bauleiter / Polier

Für die Bedienung des übernommenen Baggers sind nur unterwiesene und bereits mit dem Gerät vertraute Arbeitnehmer heranzuziehen und eine Fahrbewilligung zu erteilen.
Vor der Verwendung eines für den Benutzer neuen Gerätes hat dieser die Betriebsanleitung des Herstellers zu lesen und es ist eine gerätebezogene Unterweisung durch eine fachkundige Person zu veranlassen. (Besonderer Augenmerk bei fremdsprachigen Arbeitnehmern.)

Baustellenbezogene Besonderheiten sind im Zuge der Evaluatorung zu erfassen.

Diese Betriebsanweisung ist Bestandteil der Evaluierung und ist dem Fahrer im Zuge der Unterweisung zur Kenntnis zu bringen.

SCHUTZMAßNAHMEN UND VERHALTENSSREGELEN

Kein Gerät ohne Fahrbewilligung durch den Arbeitgeber in Betrieb nehmen.

Machen Sie sich vor der Aufnahme der Arbeiten mit den Besonderheiten der Baustelle und der Arbeitsumgebung vertraut und informieren Sie sich insbesondere über Bodenbeschaffenheit, Erd- und Freileitungen sowie bestehende oder zu erwartende Windgeschwindigkeiten.

Beim Überschreiten der max. zulässigen Windgeschwindigkeit ist die Last abzusetzen und der Bagger in Parkposition zu bringen. Bei zu erwartendem Sturm über 20 m/sec bzw. Windstärke 8 muss der gesamte Ausleger flach auf dem Boden abgelegt werden.

Nehmen Sie nie ein Gerät ohne vorherige Inspektionsrundgang in Betrieb.

Vergewissern Sie sich, dass alle Hauben und Deckeln geschlossen und alle Warnschilder montiert sind und kontrollieren Sie das Gerät auf augenscheinliche Mängel. Keine beschädigten oder in ihrer Tragfähigkeit unzureichenden Drahtseile oder Ketten verwenden.

Die Bedienungselemente dürfen nur vom Fahrersitz aus betätigt werden. Duldien Sie keine Beifahrer.

Im Gefahrenbereich des Baggers dürfen sich keine Personen aufhalten, der Aufenthalt unter schwebender Last ist verboten.

Bagger nur auf ebenem und festem Boden abstellen. Ausrüstung absetzen oder ablegen, Gerät gegen unbefugte Inbetriebnahme sichern.

WARTUNG UND INstandHALTUNG

Wartungs- und Reparaturarbeiten dürfen nur von fachkundigen und dazu beauftragten Personen durchgeführt werden.

Wartungsarbeiten nie an fahrender Maschine oder laufendem Motor vornehmen.

Vorhandene Wartungssperren verwenden.

vor jeder Arbeit an Hydraulikleitungen diese drucklos machen. Vom Hersteller vorge sehene Wartungsschutz sperren verwenden.

ACHTUNG:

Diese Anweisung ist nur ein Auszug der wesentlichsten Schutzmaßnahmen und Betriebsauflagen.

Die lückenlose Einhaltung der Betriebsanleitung des Gerätierstellers ist Voraussetzung für jeden sicheren und wirtschaftlichen Geräteeinsatz.
BETRIEBSANWEISUNG

BAGGERLADER

Hinweis für den aufsichtspflichtigen Bauleiter Polizei
Für die Bedienung des übernommenen Gerätes sind nur unterwiesene und bereits mit dem Gerät vertraute Arbeiter heranzuziehen und eine gerätebezogene Fahrerbewilligung zu erteilen.
Vor der Verwendung eines für den Benützer neuen Gerätes hat dieser die Betriebsanleitung des Herstellers zu lesen oder es ist zumindest eine Unterweisung durch einen bereits mit dem Gerät vertrauten Mitarbeiter zu veranlassen. (Besonderer Augenmerk bei fremdsprachigen Arbeiternehmern)
Achtung: Kennzeichen und Führerscheinpflicht auf öffentlichen Straßen oder Plätzen!
Bei Einsatz eines Gerätes mit Schnellwechseleinrichtung sowie einer Ausrüstung für das Heben von Einzellasten (abnahmepflichtig mit Prüfbuch und jährlich wiederkehrender Prüfung) sind dem Fahrer die diesbezüglichen Unterweisungen zur Kenntnis zu bringen und unterschreiben zu lassen. (Siehe eigene Betriebsanweisung)
Beustellenbezogene Besonderheiten sind im Zuge der Evaluierung zu erfassen.
Diese Betriebsanweisung ist Bestandteil der Evaluierung und ist dem Fahrer im Zuge der Unterweisung zur Kenntnis zu bringen.

SCHUTZMASSNAHMEN UND VERHALTENSPROBE

Kein Gerät ohne Fahrverbiligung durch den Arbeitgeber in Betrieb nehmen.

Vor dem Starten: Fahrerseite, Lenkstiel und Rückblickspiegel einstellen.

Sicherheitsgurt anlegen. (Gerät nie von außen bedienen.)
Im Leerlauf Funktionsprobe der Betriebs- u. Feststellbremse sowie Warneinrichtung durchführen.
Vor jeder Arbeitsaufnahme, auch nach Arbeitsunterbrechungen prüfen, ob sich Personen oder Hindernisse im Gefahrenbereich befinden. Im Bedarfsfall Warnzeichen geben. (Toter Sichtwinkel)
Im Fahrbetrieb Ladersaum immer in Bodennähe halten. (Bessere Sicht und Gerätetrennung.)
Mit voller Saufuchse eine Höchstgeschwindigkeit von max. 10 km/h nicht überschreiten.
Nur auf ebenerm Boden beiladen, entladen und wenden.
Stets Tragfähigkeit des Bodens berücksichtigen und ausreichend Abstand zu Baugruben halten.
Beim Befahren von Steigungen empfohlene max. Werte nicht übersteigen, querfahren und drehen möglichst vermeiden, volle Saufuchse möglichst bergseit halten.
Im Baggarbetrieb immer Abstützungen verwenden.
Erkunden Sie sich vor der Arbeit über erdverlegte Wasser-, Gasleitungen oder Stromkabel im Arbeitsbereich. Für Arbeiten unter Freileitungen vorgeschriebenen Sicherheitsabstand einhalten.
Gerät nur auf ebenerm und festem Boden abstellen. Ladersaum absenken, Heckbagger in die vom Hersteller vorgesehene festverkleidete Transportstelle bringen oder austrecken und absenken.
Feststellbremse anziehen. Fahrhebel in Neutralstellung bringen.
Motor abstellen und Zündschlüssel abziehen. Ev. vorhandene Spuren der Bedienungsebene einleugnen.
Beim Absteigen vorgesehene Tritte und Haltegriffe verwenden, nicht am Lenkrad oder den Bedienungshebeln anhalten.
Bagger gegen unbeauftragte Personen sichern.
Gerät nur bei abgestelltem Motor tanken. Kein offenes Feuer, nicht rauchen, sich vom Standort des nächsten Feuerlöschers überzeugen.

WARTUNG und INSTANDHALTUNG

Wartungs- u. Reparaturarbeiten dürfen nur von fachkundigen u. dazu beauftragten Personen durchgeführt werden.
Wartungsarbeiten nie an fahrendem Motor oder laufendem Motor vornehmen.
Ausrüstung immer absenken oder Hubarm am Stehen verwenden!
Vor jeder Arbeit an Hydraulikleitungen diese drucklos machen.

ACHTUNG

Diese Anweisung ist nur ein Auszug der wesentlichen Schutzmassnahmen und Betriebsauflagen.
Die lückenlose Einhaltung der Betriebsanleitung des Herstellers ist Voraussetzung für jeden sicheren und wirtschaftlichen Gerätebetrieb.
Böschungen

Böschungsneigung

- Die Böschungsneigung richtet sich unter anderem nach
  - der Bodenart,
  - den vorhandenen Auflasten (z. B. Verkehr, Geräte, Aushub, angrenzende Bauwerke),
  - den möglichen Erschütterungen,
  - den Grundwasserverhältnissen,
  - den Witterungsverhältnissen,
  - den geologischen Verhältnissen.

- Ohne rechnerischen Nachweis dürfen die untenstehenden Böschungswinkel nicht überschritten werden.

- Nicht bindiger oder weicher bindiger Boden
  z. B. Sande, Klische, Mutterboden

- Steifer oder halbfester bindiger Boden
  z. B. Lehm, Mergel, fester Ton, Böden mit festem Zusammenhalt

- Leichter Fels
  nicht gebröckelt und nicht vorwittert, keine zur Baugrube einfallenden Schlümpfe, ohne Klüfte

- Schwächerer Fels
  nur durch Sprengen lösbar

Böschungswinkel 80° erlaubt.
Böschungen

Standsicherheit

Die Neigungen der Böschungen sind zu verringern, wenn besondere Einflüsse die Standsicherheit beeinträchtigen (z. B. Störungen im Bodengefüge, Auffüllungen, Wasserzufüsse, Auflasten, Erschütterungen).

Bei Schichten aus unterschiedlichen Bodenarten ist es notwendig, den Böschungswinkel nach dem Boden mit der geringsten Standsicherheit anzulegen.

Ein Nachweis der Standsicherheit ist erforderlich, wenn:
- eine stellare Böschung als in D 1 angegeben angelegt werden soll;
- besondere Einflüsse vorliegen;
- bauliche Anlagen gefährdet sind.

An jedem Böschungs- oder Grabenrand ist ein Schutzschild mit einer Breite von 50 cm von Aushub, Geräten und Material freizuhalten.

Baugruben und Gräben geringer Tiefe

Bei Baugruben und Gräben bis 1,25 m Tiefe können die Wände senkrecht angelegt werden, wenn der Boden ausreichend standfest ist und keine besonderen Einflüsse vorliegen.

Vorschriften und Regeln

- BauV § Abschnitt
- M 225 Gruben, Gräben, Kläranlagen

(Stichwort: Eisenbahn, Straßenbau, Wohnungsbaubetriebe)
Künnettenverbau

Allgemeine Forderungen

- Senkrechte Künnetenwände.
- Beidseitig lastfreier Schutzzwischen mindesten 50 cm.
- Ungesicherte Künnetenwände nicht durch Baugeräte und Fahrzeuge belasten.
- Künneten mit ungesicherten Wänden nicht betreten.

Zufluss von Oberflächenwasser verhindern.
- Sich nicht an ungesicherten Künnetenwänden aufhalten (weder oben noch unten).

Der Verbau

- Der Verbau muss für die anstehende Bodenart geeignet sein.
- Er muss die auftretende Erddruckbelastung aufnehmen können.
- Er muss nach der ungünstigsten Beanspruchung bemessen werden.
- Er muss in allen Bauzuständen (Einbau und Rückbau) standfester sein.

- Er muss ausreichend dicht sein und von der Künstensorte bis mindestens 5 cm über die Geländeoberkante reichen.
- Er muss ganzflächig am Erdreich anliegen und einwandfrei hinterfüllt sein (keine Hohlräume).
- Die Künnete muss über Leitern o. A. begangen werden können.

Verbaugeräte (Beispiele)

Voraussetzungen für den Einsatz von Verbaugeräten

- Verwendungseignung des Herstellers beachten (Tauglichkeit bei verschiedenen Klimabedingungen und -fichten, Monat).
Böschungen

Standsicherheit

- Die Neigungen der Böschungen sind zu ver- 
  ringern, wenn besondere Einflüsse die Stand- 
  sicherheit beeinträchtigen (z. B. Störungen im 
  Bodengefüge, Auffüllungen, Wasserzuführen, 
  Auflasten, Erschütterungen).
- Bei Schichten aus unterschiedlichen Bodenar- 
  ten ist es notwendig, den Böschungswinkel 
  nach dem Boden mit der geringsten Standsafe- 
  tigkeit anzulegen.

- Ein Nachweis der Standsicherheit ist erforder- 
  lich, wenn 
  - eine stellte Böschung als in 0,7 angegeben 
    angelegt werden soll;
  - besondere Einflüsse vorliegen;
  - bauliche Anlagen gefährdet sind.
- An jedem Böschungs- oder Grabenrand ist ein 
  Schutzstreifen mit einer Breite von 50 cm von 
  Ausnub, Gerätet und Material freizuhalten.

Baugruben und Gräben geringer Tiefe

- Bei Baugruben und Gräben bis 1,25 m Tiefe 
  können die Wände sarkrecht angelegt wer- 
  den, wenn der Boden ausreichend standfes- 
  tig ist und keine besonderen Einflüsse vorliegen.

Accident/Incident & Near Miss Reporting, Recording and Investigation

This section covers the following topics of health and safety:

- Accident Reporting
- Accident Recording.
- Accident Investigation.

Accident has the meaning of any minor or major accident, incident or near miss in the context of this manual.

All accidents, incidents and near misses, must be recorded so that they can be investigated and analysed. Investigating a small accident, incident or near miss may well lead to preventing a future serious accident or recurrence.

Accident Reporting

The Site Health and Safety Officer (HSO) or the Project Manager shall verbally notify the Engineer of all accidents involving "serious harm" and significant "incidents" (as defined under HSE Act) as soon as practicable after the accident and submit a copy of all accident and incident reports involving Contractor personnel to the Engineer within two days of the occurrence.

In order to investigate an accident, incident or near miss, it is important that an Accident Report form (see Appendix .1), Record of Incident/Near Miss (see Appendix 2) or Incident Damage Report (see Appendix 3) is compiled. This is the responsibility of the Foreman/Shift Boss. The report will then provide the necessary facts required during the accident, incident or near miss investigation.

While preventive action following an investigation into the cause of an accident will not prevent that particular accident, by establishing the facts and being able to take corrective action, future accidents may be avoided.

Even a minor incident may arise out of circumstances that, if left uncorrected, may have all the potential for disaster. An essential element of any reporting system is that the emphasis must be on finding facts, not on finding fault or apportioning blame.
Accident Recording

FDI is legally bound by Section 25 of the Health and Safety in Employment Act of 1992 to record accidents and serious injuries in an approved Accident Register.

When any serious accident occurs to any of our employees, the FDI Health and Safety Officer must notify the Occupational Safety and Health (OSH) Service as soon as possible. FDI Health and Safety Officer must carry out an investigation and file a written report to OSH within seven days of the accident happening. This written report is entitled OSH Notice of Accident / serious harm and is located in the back portion of the OSH Accident Register (see Appendix 4).

Accident Investigation

The purpose of an accident investigation is to find the causes of the accident and to determine if the accident was caused by a significant hazard. To take steps to prevent or limit the occurrence or repetition of similar accidents, and to establish if legal obligations were fulfilled by using the Hazard Identification programme in Section 3 of this manual.

Serious or potentially serious accidents or incidents will be investigated and remedial actions taken.

This is the responsibility of the Forman/Shift Boss with assistance from the Site Superintendent and Health and Safety Officer depending on the nature of the accident, incident/near miss.

Immediate Actions after an Accident

The following steps should be taken immediately after an accident involving a serious injury:

**Important!**

If a serious injury occurs:

1) Stay calm and check for any hidden or delayed hazards.

2) Arrange immediate First Aid and call for assistance.

3) Stay with the injured person. Ensure that the Health and Safety Officer is informed.

4) Do not attempt to move the injured person unless to prevent further injury.

5) Clear the area of personnel except those authorised to be there.
6) Do not disturb the accident scene in any way until investigations have taken place and the OSH Inspector has given permission to do so.

Check List

The check list provides a means of ensuring that essential information for evaluation and reporting during an accident is available.

The following are the main aspects of an accident investigation check list:

- Details concerning the work place.
- Details of the accident.
- Details of the victim or victims.
- Details of witnesses.
- Points to be covered in the Accident Report or Record of Incident / Near miss.

At the Work Place

The following details concerning the work place should be noted:

- Check that the accident site is secure and no latent hazards exist.
- If a plan of the work place is not available, make a sketch of the accident area.
- Take necessary measurements and identify witnesses.
- Using the sketch plan, stand at points indicated by witnesses and take photographs facing the direction the witness was facing before the accident. Label the photographs when they are developed, indicating the positions of the witnesses.
- Make sure that other organisations involved in the investigation have been given the information they may require (Police, OSH, MOE, Emergency Services).
- Interview other workers who may not be witnesses but who can assist with details of training, supervision, work practices etc.
- Verify all statements given by the employer, workers and witnesses.
Details of the Accident

The following details of the accident should be noted:

- Specific location of the accident.
- Time and date of the accident.
- Time and date of the investigation.
- Weather conditions at the time of the accident.
- Hours worked by the injured person prior to the accident (was the injured person late for work).
- Exact area of the workplace where the accident occurred.
- Details of how the accident occurred.
- Was the injured person engaged on their own job or were they helping with an unfamiliar occupation?
- Who instructed the injured person to do this job - check on training and supervision?
- Were any other instructions given (by whom)?
- What was the injured person doing prior to the accident?
- How long has the injured person worked at their present occupation?
- How long has the injured person been with their present employer?
- How long has the injured person been at this workplace?
- What were the site conditions (housekeeping)?
- What were the lighting conditions at the scene of the accident?
- Was the appropriate safety equipment being worn, such as safety glasses, hard hat etc.?
- Name of immediate supervisor (in immediate control).
- Details of treatment administered to the injured person.
- Action taken to secure the accident scene and prevent recurrence.
- Identify the object or equipment that caused the injury. Note its position and serial number etc.
- If the equipment that caused the injury is mechanical plant, does it have guards in place, certificates of fitness warrants etc.
Victim (Injured Person)

The following details of the **victim or victims** should be noted:

- Full name.
- Home address (not box number).
- Age and telephone number.
- Position held in the company.
- Nature of injuries.
- Did they suffer from any disability prior to the accident?
- How much training had they received in the operation or occupation?

Witness

The following details of the **witness or witnesses** should be noted:

- Full name.
- Home address (not box number).
- Age and telephone number.
- Employer’s name.
- Occupation.
- Position held and for how long.
- Check the time of the accident.
- What was the witness doing at the time?
- Where was the witness standing and in what direction were they facing (use the sketch map)?
- In relation to the witness, where were the victim and others standing or facing at the time of the accident?
- **Own** account of what happened from all witnesses.
- Opinion as to the cause of the accident and how it could be prevented from all witnesses.
- All witnesses to sign statement at the time of the accident.
Notes:

Listen to the witnesses, don't lead them.

Witnesses may work for an employer other than that of the accident victim.

Accident Report, Record of Incident/Near Miss

The following points must be covered when compiling an Accident Report or Record of Incident/Near Miss:

- What happened.
- Where it happened.
- When it happened.
- How it happened.
- Why it happened.
- What should be done to prevent it happening again.
The Incident / Accident flow chart shows the steps to be followed after an incident or accident has occurred:

- **Incident / Accident**
  - Was a person harmed (injury or illness)
    - Serious harm
      - Contact Emergency Services
        - Notify OSH as soon as possible/obtain Site Clearance agreement
          - Fill in the Accident Register
            - Carry out an investigation (identify hazards)
              - How do we prevent/eliminate the hazard (isolation/minimisation)
                - Send prescribed form to OSH within seven days
  - Not serious harm
    - Might have harmed (near miss)
      - Fill in the Accident Register
        - Carry out an investigation (identify hazards)
          - How do we prevent/eliminate the hazard (isolation/minimisation)
            - Notify Meridian Energy Engineer

APPENDIX 4

OSH Notice or Record of Accident / Serious harm
9 Agency of accident / serious harm:
- Machinery or (mainly) fixed plant
- Mobile plant or transport
- Powered equipment, tools or appliances
- Non-powered handtools, appliances and equipment
- Chemical or chemical products
- Material or substance
- Environmental agency
- Animal, human or biological agency (not bacteria or virus)
- Bacterial or virus

10 Body part:
- Head
- Neck
- Trunk
- Upper limb
- Lower limbs
- Multiple location
- Systemic (internal organs)

11 Nature of injury or disease: (specify all)
- Fracture of spine
- Puncture wound
- Other fractures
- Poisoning and toxic effects
- Dislocation
- Multiple Injuries
- Sprain or strain
- Damage to artificial aid
- Head injury
- Disease, nervous system
- Internal injury of trunk
- Disease, musculoskeletal system
- Amputation, incl. eye
- Disease, skin
- Open wound
- Disease, digestive system
- Superficial injury
- Disease, infectious or parasitic
- Bruising or crushing
- Disease, respiratory system
- Foreign body
- Disease, circulatory system
- Burns
- Tumour (malignant or benign)
- Nerves or spinal cord
- Mental disorder

12 Where and how did the accident / harm happen?
If not enough room, attach separate sheet or sheets

13 Has an investigation been carried out? yes/no
Was a significant hazard involved? yes/no

Completely and forward it to your nearest OSH office within 7 days of incident. Keep a copy for your own records.

1 General
1.1 Objective

Extract from PHB, Section 3.4, Safety and Alarm Concept
Objective: To minimise potential incidents through prevention.

The guidelines developed in the concept must allow emergency and rescue organisations to act quickly.

Procedure: The individual procedures are listed in detail in the safety and alarm concept.

The general procedure is as follows:

- Identification of an incident
- Classification of the incident
- Alerting of the responsible organisations
- Initiation of immediate measures
- Registration / reporting of the incident

Incidents: The potential incidents are listed non-exclusively in the following:

- Gas
  - Gas incident
- Fire
  - Fire on the various building sites and installation sites
- Oil
  - Leaking oil on the building sites and installation sites (environmental protection)
- Chemicals
  - Leaking, explosion, etc. of chemicals stored on the building sites
- Electricity
  - Securing of high- and low-voltage systems
- Traffic
  - Traffic safety on the building sites
  - Safety at the points of contact with road/rail traffic
- Work safety
  - General work safety in accordance with SUVA during the tunnel heading / shaft sinking on underground sites
  - General work safety in accordance with SUVA during work on the portals, north and south junctions.

The Safety, Alarm and Rescue Concept will be coordinated by OBL in collaboration with PLF.

The section-related specific chapters will, as soon as the works have been contracted, be discussed with the relevant contractors. Subsequently these chapters will be submitted to PLF for approval. The approval will be recorded at the site managers’ meeting.

After approval, the chapters will be integrated in the Safety, Alarm and Rescue Concept. The Safety, Alarm and Rescue Concept will be updated at regular intervals parallel to the Project Manual. In the case of significant amendments / modifications, these shall be integrated as they occur.
2 Safety Concept

2.1 General

The safety measures must be coordinated and implemented as early as possible in order to be able to prevent incidents.

The various sources of danger are discussed in the following.

In the event of an incident, the procedure set out in Chapter 3 must be followed.

2.2 Work Safety

The JV is responsible for work safety. It shall appoint one person who shall be responsible for work safety on the building site. The SUVA ordinance and the EKAS guidelines must be complied with.

In particular the following items must be observed:

- Obligation to wear a hard hat
- Protective jacket when working in the road area
- The site fencing must be set up
- Crossing Flüelerstrasse is forbidden. The pedestrian bridge must be used. (BB p. 27 / Chapt. 523)

2.3 Traffic

In order to minimise the risk of accidents when working in the immediate vicinity of the road, the following measures must be implemented:

- The building site must be separated from road traffic using suitable means (e.g. Jersey elements). The site management is responsible for implementation.
- Neither building materials nor equipment must be placed on traffic surfaces. The JV is responsible for implementation of this safety measure.
- For works at or on roads, permission must be obtained from the Traffic Group of the Canton Engineering Staff (AFT) 30 days in advance.
- The site organisation must be reported to the Traffic Group of the Canton Engineering Staff (AFT) not later than 8 days before commencement of the building works.
- Unobstructed pedestrian and bicycle circulation must be guaranteed at all times.
- The Butzigrund forest road is also a hiking trail. Hikers must be able to use it without ob- struction at all times.

2.4 Migrol Petrol Station

In the vicinity of the Migrol petrol station and the internal fuel storage tanks, the works must be carried out with particular care. Welding or grinding works that produce sparks must be screened off.

In addition, the following points must be observed when working in the vicinity of the Migrol petrol station:

- The petrol station management must be informed by the building site management as early as possible about any works in the vicinity of the petrol station.
- Pedestrian and vehicle access to the petrol station must be regulated by mutual agreement between the contractor and the petrol station owner. (BB p. 16 / Chapt. 454)

2.5 Works in the Vicinity of the Railway

The conveyor belt facility crosses the SBB railway line.

The site management shall contact SBB as early as possible to discuss the safety measures. The requirements of SBB must be complied with.
The site management is responsible for coordination of the safety measures when installing the conveyor belt crossing.

The requirements of the Special Provisions, Chapt. 454 (p. 15/16) and Annex 2 (BB) must be complied with.

2.6 High-voltage Cables
There are high-voltage cables within the building site area.

The JV is responsible for ensuring that personnel and machinery (especially cranes, excavators, etc.) keep the minimum distance as set out in the SUVA regulations.

In sensitive areas, this shall be ensured by using protective scaffolding.

2.7 Utilities
Prior to commencement of the building works, the JV shall obtain information about the quantity and location of utility cables and pipelines from the relevant utility owners.

2.8 Works in Groundwater
The building site is located in a Class A Water Zone.

The JV is responsible for compliance with all the requirements of the Afu. (BB Annex 3)

It is also responsible for functioning water retention in the construction pits.

2.9 Gas
During the tunnel heading, gas deposits must be expected in accordance with the geological report (Annex G, Chapt. 6 of the Submission).

The heading breast must be well ventilated. Especially after longer work interruptions during which the ventilation is shut down, the entire tunnel must be ventilated properly before it may be accessed. The SUVA “Guideline for the Prevention of Accidents due to Fire and Explosion during Construction Works in Rock Layers Containing Natural Gas” must be complied with (BB p. 40). The gas concentrations must be monitored (as set out in BB p. 38).

The Safety Commission Gas (Chairman Dr. R. Wyss) will supervise the heading phase and issue appropriate instructions.

If gas deposits are identified, the JV must notify the site management immediately. The site management shall ensure that the gas expert visits the site immediately to assess the situation.

2.10 Environment
The instructions in the Special Provisions, Chapter 480 ff. must be complied with.

INTEGRAL SAFETY PLAN

(Versions 07/06 2003)

REVISED 26. 05. 03

SATCO

3717 BLAUSEE – MITHOLZ
Table of Contents

1. **Alarm Organisation:**
   - Telephone lists
   - Emergency services
   - Organisational charts
   - Major incidents / Satco - internal

2. **General:**
   - Fundamentals
   - Hazard zones
   - Risk analyses
   - Codes of measures (supplement pneumatic operation)
   - Flue gas concept

3. **Work safety:**
   - Employees
   - Fire (Agreement Rescue Scouts)
   - Gas (Instructions)
   - Water (Karst)
   - Environment
   - Material storage sites

4. **Safety / rescue measures**
   - Fire
   - Gas
   - Water (Karst)
   - Environment
   - Operating instructions escape container
   - Tunnel ambulance
   - Ex - protected vehicle
   - Emergency service planning

5. **Avalanche service:**
   - Map
   - Organisational chart
   - Alarm levels
   - Evacuation concept

6. **Blast heading:**
   - Use of explosives
   - Excavation
   - Annex 1, Storage of Explosives
   - Safety data sheet DYNO

7. **Water protection:**
   - Drainage concept / water protection concept
   - Storage of hazardous goods
   - Personnel instruction

8. **Waste disposal:**
   - Multi-container concept
   - Disposal concept

9. **Access control:**
   - Concept
   - Visitors
   - Confirmation concept

10. **Annex:**
    - Safety-relevant installations
    - Fire-fighting installations
    - Escape routes
    - Access emergency services
    - Gas safety concept
    - Ventilation concept north before and after breakthrough OR
    - Fire safety - additional installations / alarm devices

Table 3: General Safety Rules

Employee Responsibility

1. No person under the influence of alcohol, non prescribed drugs or in possession of alcohol or illicit drugs shall enter the property. Employees must inform supervisor if they are on prescribed medication prior to shift.

2. No person shall wilfully damage or, without proper authority, remove or render useless any electrical, fire fighting rescue or first aid equipment, deface, destroy any signs, remove guards or disarm a safety device.

3. No person is to tamper with any machinery or equipment in or about the project.

4. No pushing, scuffling, horseplay, fighting or verbal abuse is permitted.

5. Report ALL injuries, accidents and incidents to your supervisor at once. If medical attention is sought as a result of an injury at work the doctor must fill out the WSIB “Functional Abilities Form” and a copy of this form is to be given to your immediate supervisor.

6. All workers have a responsibility to actively participate in the company safety program and a legal obligation to abide by the safety rules and regulations of the Occupational Health and Safety Act.

7. Clothing covering the full trunk, shoulders and legs is required. Shorts, mid-drift shirts or ragged clothing is not allowed. Neck chains, rings and all other loose jewellery is not to be worn where they present a risk for injury.

8. No use of personal cell phones during company time.

9. No smoking in any company building, trailer or marine vessel.

Personal Protective Equipment

1. All workers, visitors and delivery personnel shall wear CSA approved hard hats on all construction sites.

2. Respiratory protection is to be worn as circumstances warrant. Employee to see supervisor for type of respirator required.

3. Eye protection is to be worn as required to reduce the risk of eye injury. Specific classes of eye protectors shall be matched to specific hazards.

4. Hearing protection is to be worn as required.

5. Foot protection must meet Federal and/or Provincial regulations and must be worn by all workers, visitors and delivery personnel on all construction sites and in all shops.

6. Fall Arrest Systems are to be worn to provide maximum safety from falls.

7. Hand protection suitable to the hazard is to be used.

**Table 5: Visitor Orientation**

Prior to any visits commencing a safety orientation must be carried out. This will involve a short safety talk identifying the major hazards.

Visitor Safety Rules:

1. Visitors are required to sign Release from Liability Statement. Safety equipment will be issued as required. A visitor pass will be issued which must be prominently worn.

2. No visitor is to go around site unaccompanied. They will be escorted through the works by a company representative and must take notice of all instructions given by the representative.

3. For repeat visits an assessment will be made and further instruction given to explain any variance in circumstance.

4. **NO PHOTOGRAPHY WILL BE PERMITTED BY VISITORS UNLESS APPROVED BY THE WORKPLACE MANAGER.**

Table 7: Emergency Procedures for Marine Work

(Workers to read and sign – one copy to be sent to head office)

The following procedures are to be initiated, where appropriate.

Emergency Phone Nos.

911  Fire, Police & Ambulance
MOL  (416) 235-5330 (Toronto)
Canadian Coast Guard (Marine Communications & Traffic Services: MCTS)
Sarnia  (519) 337-6572
Prescott  (613) 925-0618
Thunder Bay  (807) 345-4618
DIALING 16 on your Bell Cellular, Cantel or Thunder Bay Cellular Telephone.

VHF MARINE RADIO CHANNELS

Channel 16 Distress, Safety & Calling
Channel 21B & 83B Weather & Navigation

HAND HELD PORTABLE RADIOS

Position 1 CH7A  156.35 MHz  Marine Construction
Position 2 CH16  156.80 MHz  Distress Safety Calling
Position 3 CH21B  161.65 MHz  Weather – Listen Only.
Position 4 CH83B  161.77.5 MHz  Weather – Listen Only

Rescue Equipment: (On Barges & Tugs)

1. Rigid stretcher unit, complete with securing harness, neck brace and lifting attachments.
2. Dedicated Fire Extinguishers, and First Aid equipment (As required by CCG. Regulations). A first aid kit, blankets, fire extinguisher, stretcher & Confined Space Entry Equipment will be maintained on the Working Barge.
3. An outside Telephone will be maintained to enable the Emergency Services to be called. (See list)
4. A suitable boat, equipped with ring buoy attached to fifteen metres of polypropylene rope that is 9.5 millimetres in diameter, a boat hook, a life jacket for every person in the boat. The boat shall be power driven if the water is likely to be rough or swift.
5. An alarm system: boat whistle, bell, horn, or ship to shore radio.
6. An Oil Spill Kit
7. Immersion Suits, Life Jackets, Inflatable Life Raft, Distress Signals (Flares): List depends on vessel size, type & area of operation, as required by CCG. Regulations.

Medivac

In the event of an injured person, an assessment will be made by the person in charge as to the severity of the injury and the necessity for outside assistance, if outside assistance is required, give the following information:

1. Your name.
2. Name of injured person.
3. Location of incident.
McNally Construction Inc.

4. What the injuries are to the best of your knowledge.
5. If 911 services are required
6. Any special equipment required, such as stretcher, backboard, splints, additional first aid equipment etc. to be brought to the barge.

For an injured worker the following steps will be taken:

1. A competent person, fully trained in first aid will take charge of the situation.
2. Call for assistance from fellow workers.
3. Assess the hazards at the scene; make the area safe for yourself and others.
4. Identify yourself to the casualty as first aid person and offer assistance.
5. Quickly assess the casualty for life threatening conditions. (ABC).
7. If Paramedics are required at the scene of injury, make arrangements for their transport by boat, and send a person to direct ambulance to the boat.
8. If injured person is capable of walking, send a person with the casualty to assist him to the boat to be taken to shore.
9. If the injured person requires a stretcher, send a person ahead to insure there is a clear space on the boat to place the stretcher.
10. If ambulance is not required, make arrangements for a pick up to be available at the shore to transport the person to the office, or the Hospital, depending on the injury.
11. Should the accident involve a fatality or critical injury, the MOL shall be notified immediately. Additionally, the accident scene must not be interfered with or disturbed. Nothing at the scene shall be destroyed, altered or carried away, except that required to assist the casualty, until the MOL inspector gives permission.

**Man-Overboard**

In the event of a man-overboard incident, the following process will be initiated:

1. Sound alarm – 3 long blast on Whistle or general alarm ‘Bell.
2. Locate and maintain visual contact with person.
3. Deploy life ring, Buoyant life line and self igniting light
4. Manoeuvre the vessel to permit recovery.
5. Place engines in neutral when next to the person.
6. Effect recovery of person in a safe manner.
7. Administer appropriate first aid. (Follow procedures for MEDIVAC).

**Fire**

The following should be initiated in the event of a fire onboard:

1. Sound the alarm, continuous ringing of general alarm, horn or whistle.
2. Identify type and location of fire.
3. Contact appropriate shore authorities.
4. If crew cannot put out the fire, remove crew and tow equipment to dock so fire dept can fight fire.

Abandon Ship
The decision to abandon ship is the responsibility of the Captain or senior person onboard, given by verbal command only. The vessel is equipped with life saving equipment applicable to her size and function. The following process should be initiated once abandon ship order has been given:

1. Immersion Suits to be worn when ordered to or life raft is deployed.
2. Personnel to proceed to their abandon ship station.
3. Ensure Raft latches are released.
4. Ensure painter is secured to a strong point.
5. Ensure the water below the raft is clear.
6. Deploy life raft, as boat drill requires.
7. Board raft.
8. Manoeuvre clear of vessel.

Procedure for Fuelling Vessels
1. Material Safety Data Sheet to be reviewed by workers handling fuel.
2. The on site storage of bulk fuel is to be restricted to the delivery truck and fuel storage tanks aboard the vessel.
3. Fuelling equipment to be grounded during fuelling operations, Fuel nozzle is grounded to steel vessel that is in the water.
4. Fuel truck to have ABC fire extinguisher.
5. Vessel to be equipped with fire extinguishers.
6. All equipment to be in good working order and free of leaking seals to prevent lubricants from entering the environment.
7. In the event of any chemical spill, immediately notify appropriate authorities.
8. Fuel truck to have hose nozzle with a positive shut-off.
9. Fuelling port on vessel to have a sealed cap.
10. Vessel is equipped with absorbent pads in the event of a minor spill.

Hazardous Materials Spills
Upon discovery of a hazardous materials spill, personnel will assess the situation to determine the severity, and potential for escalation of the danger. At this point it will be decided whether action can be taken to control the situation using vessel personnel or to request assistance.

If it is decided that the incident could be taken under control immediately, steps are to be taken to contain the spill and initiate cleansing operations. Priority of containment is to prevent liquid from spilling overboard. The spill is to be contained by the use of environmental kits retained onboard and if possible and necessary, coordination with the bridge to induce appropriate roll and pitch or to minimize ship motion. Cleansing will include transferring the material to a holding area. In addition, residue will be soaked up with rags and other available absorbent material.
McNally Construction Inc.

In the event that the situation cannot be controlled immediately, and potential exists for increased danger, assistance will be requested at once. The first priority will be to secure the safety of the vessel and personnel and to pursue all action necessary to prevent environmental pollution. Appropriate authorities shall be notified of the situation and advised of the vessels position and weather conditions and the following:

1. Approximate location and size of the spill.
2. That the Person in charge contacting Applicable Response Organization is the person authorized to implement the arrangement. (See contact list)
3. The name of the vessel.
4. The type of liquid or material involved.

Heavy Weather
The weather conditions will be monitored via the marine weather channel. When heavy weather conditions are predicted the vessels shall make for protected waters or ensure that they are moored in a satisfactory condition to ride out the weather conditions.

The tug designated as the dredge tug shall be assigned the responsibility of safety boat

Certification
I hereby certify that I have read and understand the above emergency procedures.

✓ Check when completed

☐ Workplace Notice
Notice of Workplace No. ___________________________
Notice for tunnels, shafts caissons and Cofferdams No. ___________________________
Notice for Sub-Contractors ___________________________
Notice of Project (Diving) ___________________________

☐ Structural Drawings to MOL (Shaft, tunnel, supports, forms etc.)

☐ Copies of Policy and Program on site (along with Procedures for that job)

☐ Orientation Packages (to include Tables 1 – 5 and Tables 10 and 18 if applicable) and Hiring Forms

☐ Accident/Incident Reporting Form (Table 11)

☐ WSIB Functional Abilities forms (As per Table 4 and Back to Work Policy Sec1.11)

☐ Tool Box Talk Forms (Table 13) and Safety Talk suggestion cards

☐ Monthly Site Inspection Forms (Table 14 for Job Sites)

☐ Safety Citations (Table 19)

☐ Forms for Marine Emergency Procedures (Table 10) -if applicable to job

☐ Confined Space Permits, (Table 16) Confined Space Units & Gas Testers (if required)

☐ Visitor Forms (Tables 7 and 8)

☐ Personal Protective Equipment as required (Hard Hats, gloves, rubber boots, rain suits, eye protection, hearing protection, Fall Protection, Dust Masks, Reflective Vests etc.)

☐ WSIB Poster “In all cases of Injury/Disease” – to be posted in an inconspicuous place

☐ McNally International Inc. Poster for Reporting of Accidents (Table 20)

☐ WHMIS book (obtain from Head Office) and put in a common place (ie/ lunch room or first aid room)

☐ First Aid – Boxes as required by Regulation 1011 (See Section 1.10.6 of the Policy and Program), List of people with up-to-date First Aid (Certificates to be posted)

☐ Post names of Joint Health and Safety Committee members or Health and Safety Representative (whichever applicable – See Section 1.5 in the Policy and Program)

☐ Fire Extinguishers and flashlights

☐ MOL forms for Sub-contractors and a copy of our Policy and Program for Subs

☐ Log Books, foreman’s diary, operating manuals/instructions etc for equipment,

☐ Oil Spill kit
☐ Eyewash station

☐ Full Body harnesses and lifelines (as required)

☐ Copies of Union Agreements (where applicable)

☐ Emergency Contact List - Posted in an inconspicuous place (to include 911, Police, Ambulance, Fire, Spill Centre, Gas, Hydro, Sewer, Water, Cable, Ministry of Labour, Hospital, Canadian Coast Guard etc – See Section 5.3 in the Policy and Program)

☐ Drawing showing route and phone number to nearest Hospital to be posted near exit door(s)

☐ Copies of the Occupational Health and Safety Act (OHSA) and regulations (Industrial for Shops and Offices and Construction for Job Sites) and any other acts/regulations as required by the OHSA.

☐ Rescue Procedures as applicable to job

☐ Signs for Hard Hats and Safety Boots

☐ Danger construction signs and other signs as required

☐ Bulletin Board for workers

☐ Sub-contractor /Supplier Orientation Checklists (Table 6) and Copies of Form 1000 for Sub-contractors to complete if required

To be signed by Workplace Manager/Superintendent and a copy sent to Head Office (Safety Co-ordinator) indicating that the above items are on site unless otherwise indicated:

Rating Hazards = Severity x Frequency divided by 2

Severity = # from 1 to 10 where 10 is life threatening and 1 is minimal harm

Frequency = # from 1 to where 10 is worker does task all day and 1 is occasional

Class A – Rating is between 40-50 – A condition or practice that could result in death, permanent disability or expensive damage

Class B – Rating is between 29-39 – Serious injury or illness or major property damage that is disruptive but not as serious as Class A

Class C – Rating is between 1-24 – Minor injury or illness that is non-disabling or property damage that is non-disruptive

Supervisors: completion of this checklist should not be construed as indicating compliance with all requirements of OHSA and the construction regulations but instead as a starting point for your site. Supervisors should review all relevant legislation and regulatory requirements. If you require additional information or help to comply with safety regulations on your site please contact the Health and Safety Co-ordinator in Head Office.

**Rating Hazards** = Severity x Frequency divided by 2

**Severity** = # from 1 to 10 where 10 is life threatening and 1 is minimal harm

**Frequency** = # from 1 to where 10 is worker does task all day and 1 is occasional

**Class A** – Rating is between 40-50 – A condition or practice that could result in death, permanent disability or expensive damage

**Class B** – Rating is between 29-39 – Serious injury or illness or major property damage that is disruptive but not as serious as Class A

**Class C** – Rating is between 1-24 – Minor injury or illness that is non-disabling or property damage that is non-disruptive

**PERMIT SPACE HAZARDS**
(Check appropriate box to indicate if item is a potential hazard)
- Oxygen deficiency (less than 19.5%)
- Oxygen Enrichment (greater than 23.5%)
- Flammable gases of vapours (greater than 10% of LFL)
- Air born combustible dust (meets or exceeds LFL)
- Toxic gases or vapours
- Mechanical hazards
- Electrical shock
- Materials harmful to the skin
- Engulfment
- Hotwork
- Other

**ENTRY/WORK EQUIPMENT**
(Indicate equipment and/or PPE needed)
- Hard Hat
- Work Boots
- Safety Glasses
- Hearing Protection
- Gloves
- Full Body Harness
- Respirator Protection
- Communication
- Rescue: S.C.B.A.
- Tripod
- Oxy-K
- Lifeline

**PREPERATION FOR ENTRY**
(Check which of the following steps have been taken)
- Notify personnel in affected work areas
- Isolate space by Lockout/Tagout
- Isolate space by blanking/blinding
- Purge/Clean
- Ventilate
- Barriers
- Signs
- Atmospheric Test
- Pre-Entry briefing (hazards/control methods)
- Notify Contractors
- Specify Other:

Table 18: Drug & Alcohol Acknowledgement Form

I hereby acknowledge that I have received, have reviewed, and understand the Drug and Alcohol Use Policy ("the Policy") of McNally International Inc. ("the Company") and I hereby agree to comply with all of the Policy's terms and conditions.

I understand and agree that my compliance with the terms of the Policy has been properly mandated by the Company for the safety of my co-workers, the public, and myself.

I hereby authorize substance abuse professionals and testing officials to release any information to the Company that is reasonably necessary to the implementation of the purposes and provisions of the Policy. I further hereby consent and authorize the Company to release to substance abuse professional and testing officials any information that is reasonably necessary to the implementation of the Policy.

I understand and agree that my compliance with the Policy is an essential and required term of my employment with the Company. I further understand and agree that my employment or continued employment with the Company is conditional upon me signing this Acknowledgement.

Is hereby notified of a violation of safety rules. This notice is part of McNally International Inc.’s disciplinary action program.

Violation: ________________________________________________________________

Violation Issued By: _______________________________________________________

Disciplinary Action Taken:

A. First Citation
   - Warning of violation only
   - Serious - Suspended 3 consecutive working days without pay
   - Severe or life threatening - Termination

B. Second citation
   - Automatic 3 day suspension without pay
   - Severe or life threatening - Termination

C. Third citation
   - Within 6 month period or history of repeat violations - Termination

Employee’s Signature ___________________________ Foreman’s or Witness’s Signature ___________________________

Date: ___________________________
If you are injured at work...

1. **Tell Your Supervisor**
   Details of your injury
   Even if it is small and you do not need medical attention - Your supervisor will need to log the details.
   Obtain a "Functional Abilities Form" from your supervisor in case you

2. **Tell Your Employer**
   Details of Medical Aid or need for Light Duty Work
   Your supervisor must know if you seek medical aid in order to fill out the required paperwork for Head Office & the WSIB
   If Light Duty Work is required we will do our best to accommodate you

3. **Tell Your Doctor**
   Your injury is work related & you can be assigned light duties
   Get your doctor to complete the "Functional Abilities Form"
   Return this form to your supervisor so he can immediately assign you Light Duty Work until you recover

1.0 CORPORATE POLICY STATEMENT

Management of McNally Construction Inc. is vitally interested in the health and safety of our employees. Management will meet or exceed the requirements of the Occupational Health and Safety Act and Regulations and work with the Joint Health and Safety Committee as outlined in the Act. As required by the Act Management will ensure that equipment, material and protective devices as prescribed are provided and in a safe working condition and that measures and procedures prescribed are carried out at each worksite. Protection of employees from injury or occupational disease is a major continuing objective. McNally will make every effort to provide a safe and healthy work environment.

All supervisors and workers must be dedicated to the continuing objective of reducing risk of injury. Supervisors will be held accountable for the health and safety of workers under their supervision. Supervisors are responsible for ensuring that machinery and equipment are safe and that workers work in compliance with established safe work procedures. Workers must receive adequate training in their specific work tasks to protect their health and safety.

Every worker must protect his or her own health and safety by working in compliance with the law and with safe work practices and procedures established by the company.

It is in the best interest of all parties to consider health and safety in every activity. Health and Safety is a daily responsibility of every person within this company. Commitment to health and safety must form an integral part of this workplace, from all levels of supervision to all workers.

Signed: ___________________________ Date: ___________________________

Patrick McNally, President

2.1 Scope and Purpose – Health and Safety Program

The purpose of this program is to reduce and eliminate accidents. A safety program is a success when all personnel do routine jobs in a safe manner and new tasks are not done until the method is a safe one. There is never a reason to get a job done, that time can not be taken to do it safely.

Management’s desire is to provide a safe work atmosphere, safe equipment, proper materials, and safe methods and practice at all times. Each person who conducts company business no matter their position needs to accept this responsibility as well. The information contained herein, is for all McNally work sites and offices regardless of task at hand.

2.2 Internal Responsibility System

McNally Construction works on the basis of an Internal Responsibility System meaning that everyone, both management and workers, are to work together to ensure that every location is a safe and healthy place of work. Each individual work site is in the best position to identify safety problems and to help develop solutions. This shares the responsibility of eliminating hazards in the workplace between
management and workers and has an interlocking set of duties, obligations and rights for each party. Each supervisor from foreman to project manager is responsible to ensure that operations run in a safe manner. Each employee is responsible to report existing or possible hazards. By working together we will be able to achieve a healthier and safer work environment at all locations.

2.2.1 Health and Safety Reporting Structure

2.2.2 Networking

Networking is defined as “An extended group of people with similar interests or concerns who interact and remain in informal contact for mutual assistance or support”.

In an effort to stay up-to-date on safety policies and procedures and to benefit from the experience of others, McNally will implement and maintain networking as part of its safety practice. By sharing this information in all levels of the company the Internal Responsibility System will be strengthened.

The Safety Management Team and/or Supervisory Personnel will complete a minimum of 5 forms of networking each year. This can include but will not be limited to:

- Training by other organizations
- Safety Conferences, Incentive programs and Tradeshows
- Sharing safety information with other companies either by exchanging policies or meeting in Joint Venture settings or calling for the reason of obtaining/sharing info.
- Research information on the Internet
- Safety Magazines, bulletins etc
- Participating in Organizations such as ORBA, OSWCA, IAPA, CSAO

2.3 General Legal Duties

All employers must comply with and provide for the health and safety of their employees in accordance with the provisions of the “Occupational Health and Safety Act” and applicable regulations. Each person in the workplace has duties and responsibilities under the Act according to their position.

The general legal duty of both the employer and the supervisors is to take all reasonable precautions to protect the workers' health and safety. For workers the legal duty is to work in accordance with the Act and its regulations. All employees are required to work in a manner that will not cause harm to themselves or others. All hazards must be reported to your supervisor.

The Occupational Health and Safety Act (OHSA) was established to protect workers against health and safety hazards on the job.
2.4 Officers and Directors
The Officers and Directors will take all reasonable care to ensure that McNally Construction complies with Occupational Health and Safety Legislation as well as the orders and requirements of the Ministry of Labour Personnel in their administration of the Occupational Health and Safety legislation.

2.5 Senior Management
Senior Management will:

- Ensure that a safety program is maintained
- Appoint only competent supervisors
- Ensure equipment, materials and protective devices are as required by the Act and kept in good working condition.
- Only employ those individuals of the legal minimum age
- Post in the workplace a copy of the Occupational Health and Safety Act
- Attend Monthly Management Health and Safety Meetings

2.6 Supervisory Personnel

2.6.1 Competent Supervisor
A competent supervisor as defined by OSHA (Section 1 – Competent Person) is a supervisor that is:

- Qualified because of knowledge, training and experience to organize the work and its performance,
- Is familiar with the Act and the regulations that apply to the work, and
- Has knowledge of any potential or actual danger to health or safety in the workplace

Supervisors will be designated, most supervisors will be promoted from within the trained workers. Training will be given to assist supervisors in their roles. Those employees anticipated to be future supervisors will also receive supervisory training. Refer to chapter 9.0 “Training” for supervisory training.

2.6.2 Supervisory Responsibilities
Supervisory Personnel, includes Project Managers, Superintendents and foremen, will:

- Lead by example at all times for fellow workers.
- Ensure the health and safety of their workers is protected
- Conduct and document job orientation training for all new employees and those returning to the site after an absence.
- Ensure workers have been advised of any potential or actual danger to the workers
- Supplies and enforces the use of proper protective equipment and tools for the job.
- Be familiar with and enforce all safety program rules.
- Ensure workers and subs. are working in accordance with the program and the Act.
- Quickly ensure that first aid or medical treatment is administered to anyone on crew that is injured, promptly investigate and document all accidents and ensure that appropriate corrective action is taken to prevent a reoccurrence.
- Assist and co-operate with the Joint Health and Safety Committee or Health and Safety Representative in completing their duties.
• Hold documented weekly “Tool Box Safety Meetings” with workers which consist of a weekly toolbox talk discussing a relevant topic or safety item with workers. This must be completed for all shifts where applicable.
• Complete all supervisory paperwork on time and in a coherent manner.

2.7 Safety Coordinator

• Responsible for maintenance of all health and safety programs and procedures
• Reports directly to Senior Management and maintains a direct line of communication with all supervisory personnel for the purpose of advice, recommendation and consultation on health and safety topics.
• Conducts regular surveys, inspections and routine monitoring of operations to ensure safe practices. Recommends observations for follow-up and action
• Co-ordinate safety activity with the owner, sub-contractors etc.
• Arranges for worker and supervisor training as required.
• Supports the efforts of the Joint Health & Safety Committee/Worker Trade Committee and Health and Safety Reps.

2.8 Workers

2.8.1 Worker Responsibilities

Workers are expected to follow the Procedures and Policies in this manual and work in compliance with the Provisions of the Health and Safety Act and Regulations.

Workers are to use or wear the equipment, protective devices or clothing as the employer directs.

Workers are to report to the supervisor any equipment defect of which the worker is aware of, any contravention to the Act or the existence of any potential or known hazard.

The safety information in this manual does not take precedence over the Occupational Health and Safety Act and Regulations.

2.8.2 Worker Rights

To balance the employer’s given right to direct the work force and control the production process in the workplace, the Act gives the worker three basic rights.

1. The Right to Participate – Workers have the right to be part of the process of identifying and resolving workplace health and safety concerns. This right is expressed through worker membership on the Health and Safety Committee or Representative as well as the opportunity for discussion in Tool Box Talks and Safety Meetings.

2. The Right to Know – The worker has the right to know about any potential hazards to which they may be exposed. In short, the right to be trained and have information on machinery, equipment, working conditions, processes and hazardous substances. McNally has two methods of getting hazard information to its employees – weekly tool box talks and WHMIS (Workplace Hazardous Materials Information System) training. Workers should report hazards they become aware of to their supervisor immediately.

3. The Right to Refuse Unsafe Work – When a worker believes that a situation/task is dangerous or outside of their physical limitations, they have the right to speak up and refuse this work. This privilege is to be taken seriously and not abused. A work refusal must follow proper procedures – these are detailed in Chapter 8 of this policy and program.
2.9 Observing Unsafe Acts

Our first obligation to our co-workers, the company and ourselves is to work in a safe and responsible manner at all times. To allow a co-worker or an individual from outside the company to perform an unsafe act may put your life or the lives of others in danger.

To knowingly stand by and watch an unsafe act be performed is in strict violation of this Health and Safety Policy.

2.10 Company Vehicles

2.10.1 Driving Privileges

Driving a company vehicle is viewed as a privilege not a right. A driver’s abstract will be obtained from the Ministry of Transportation prior to any worker obtaining the privilege of driving a company vehicle. If an employee has a bad driving record than driving privileges using a company vehicle will be revoked. See defensive driving below for additional information on driving privileges.

2.10.2 Maintenance

Employees assigned a company vehicle are expected to do routine checks of their vehicle and report any concerns to their supervisor immediately. Regularly scheduled maintenance such as oil changes must also be completed. It is important that your vehicle is operated in a safe condition, please make sure that all safety concerns regarding your vehicle are addressed by either your supervisor or the equipment manager in Head Office.

2.10.3 Vehicular Accidents

Should an accident in a company vehicle occur:

1. Stop, turn off the vehicle and protect the scene from further damage.
2. Assist the injured if possible, call 911 if serious injuries occurred.
3. Call authorities and obtain all the information necessary to complete the Driver Report Forms.
4. Report this accident to the Health and Safety Coordinator or if not available your divisional manager.
5. Avoid discussing the accident or accepting responsibility with anyone except a law officer, your employer or McNally’s Insurance Company.

In the glove compartment of all company vehicles is a Vehicle Accident Reporting form. It is the responsibility of the person assigned to the vehicle to ensure there is a copy of this form in the vehicle at all times, along with a copy of the ownership and insurance slips.

Should an accident occur in a company vehicle it is important that all essential information is obtained and the Vehicle Accident Reporting form is designed to ensure this. This accident must be reported to the Health and Safety Coordinator in Head Office no later than the first working day following the accident.

2.10.4 Defensive Driving

All employees are expected to drive in a safe, law abiding manner. Because safe driving affects us all whether we drive a company vehicle or not, McNally will promote safe, defensive driving throughout the year by completing one tool box talk each month on a safe driving topic on all job sites. These talks will cover such topics as safe braking, driving in a diversity of weather conditions, circle checks, maintenance of vehicles, watching for pedestrians and other related topics.
Driver's abstracts will be collected on a yearly basis for all employees' who regularly drive a company vehicle. Should an employee's driving record dramatically decrease from one year to the next that employee will be required to take a certified defensive driving course and improve their driving record prior to the next yearly abstract review. Should this same employee’s record decrease even further on this second review, driving privileges will be revoked until the personal driving record has been improved.

2.11 Review and Posting of Information
McNally will review accident investigations, hazard assessments and accident reports on a monthly basis. These reports will be discussed at Joint Health and Safety committee meetings, supervisory meetings and management safety meetings, with discussion being documented in the meeting minutes.
McNally will ensure that any MOL orders and the minutes from the Joint Health and Safety Committee meetings are posted for employees to review. All employees are encouraged to read the posted information to keep informed regarding safety matters affecting their site. Safety statistics will be kept in the form of a spreadsheet to track safety performance improvement both by site and corporately.

2.12 Management Health and Safety Meetings
Senior Management will meet approximately once a month. Attendees at this meeting should include but are not limited to the President, Secretary-Treasurer, Division Vice-Presidents and the Health and Safety Co-ordinator. Agendas/Minutes will be kept using a numerical system. All new issues will be assigned a number for example issue 1 in meeting 18 would be 18.1, issue 2 at this same meeting would be 18.2. This will allow tracking how long an item has been in the old business section.

2.13 List of Safety Items Required for each Workplace
Table 9 “Safety Items required on Site for Workplace Managers/Supervisors” as found in the Tables package of this Program, outlines in detail all items required for every job site from a Health and Safety perspective. All items can be acquired from Head Office. Table 9 must be signed by the Supervisory Personnel once all items are on site and this form should be returned to the Health and Safety Co-ordinator in Head Office within the first 2 weeks of the project commencing.
3.0 ENFORCEMENT
3.1 Progressive Disciplinary Program

3.1 Progressive Disciplinary Program
McNally believes in a progressive disciplinary program. The goal of this program is to provide supervision with a tool to educate workers in areas where safety risks are being taken.

The steps of Disciplinary Action will be as follows:

1. First Citation – Warning of Violation (For Serious or Life Threatening situations penalty could be suspension without pay or termination)
2. Second Citation – Automatic 3 day suspension without pay (Severe or Life Threatening – Termination)
3. Third Citation – Within 6 month period or for a history of repeat violations – Termination
4. Any worker receiving a 3-day suspension will be counselled on why disciplinary action was taken and how the individual's attitude or behaviour can be adjusted to a positive approach.
5. Any worker who receives either three (3) warning citations or two (2) 3-day suspensions will be terminated.

3.2 Documentation
Disciplinary action for contravention of safety rules and regulations will be documented on Table 19 “Safety Citation” and copies are to be given to the workplace manager and the safety co-ordinator.

3.3 Conduct
Examples of health and safety violations where any employee will be disciplined or subject to discharge:

1. Violation of health and safety rules, policies, or procedures
2. Stealing or wilful destruction of company property.
3. Violence, harassment, horseplay or disorderly conduct on company property.
4. Coming to work under the influence of drugs or alcohol or bringing these items to work.

3.4 Ministry of Labour (MOL) Visits
If the company's internal responsibility system fails to address adequately the health and safety issues in the workplace, or if the Act and regulations are not being followed, the MOL has the authority to enforce the law and to see that obligations to the Act and Regulations are being complied with.

An Inspector from the MOL, for the purposes of carrying out his or her duties and powers under the Act, may enter a worksite at anytime without prior warning or search warrant.
When the Inspector arrives on your site, the worker’s representative and the site supervisor must accompany the inspector. If a worker is asked a question that they can not competently answer than the question is to be directed to someone who can.

While on site the inspector is required to comply with our Safety Program and wear appropriate personal protective equipment.

Always be kind and courteous to the inspector. Remember that they are there to do a job and can be a help to us. Answer questions asked to the best of your ability. Ask the inspector relevant questions to show that you are willing to comply and eager to learn.

If an inspector gives orders they must be dealt with immediately. A copy of the orders given must be sent to Head Office along with a report on what was done for compliance to the orders.

For additional information on dealing with the Ministry of Labour inspectors for Critical Injuries see Chapter 10 in this Policy and Program.

4.1 General Workplace Safety

These general safety rules can also be located in Table 3 of this policy and program.

Employee Responsibility

1. No person under the influence of alcohol, non-prescribed drugs or in possession of alcohol or illicit drugs shall enter the property. Employees must inform supervisor if they are on prescribed medication prior to shift.

2. No person shall willfully damage or, without proper authority, remove or render useless any electrical, fire fighting or first aid equipment, deface, destroy any signs, remove guards or disarm a safety device.

3. No person is to tamper with any machinery or equipment in or about the project.

4. No pushing, scuffling, horseplay, fighting or verbal abuse is permitted.

5. Report all injuries, accidents and incidents to your supervisor at once. If medical attention is sought as a result of an injury at work the doctor must fill out the WSIB “Functional Abilities Form” and a copy of this form is to be given to your immediate supervisor.

6. All workers have a responsibility to actively participate in the company safety program and a legal obligation to abide by the safety rules and regulations of the Occupational Health and Safety Act.

7. Clothing covering the full trunk, shoulders and legs is required. Shorts, mid-drift shirts or ragged clothing is not allowed. Neck chains, rings and all other loose jewellery is not to be worn where they present a risk for injury.

8. No use of personal cell phones during company time.

9. No smoking in any company building, trailer or marine vessel.

Personal Protective Equipment (PPE)

1. All workers, visitors and delivery personnel shall wear CSA approved hard hats on all construction sites.

2. Respiratory protection is to be worn as circumstances warrant. Employee to see supervisor for type of respirator required.

3. Eye protection is to be worn as required to reduce the risk of eye injury. Specific classes of eye protectors are to be matched to specific hazards.

4. Hearing protection is to be worn as required.
5. Foot protection must meet Federal and/or Provincial regulations and must be worn by all workers, visitors and delivery personnel on all construction sites and in all shops.

6. Fall Arrest Systems are to be worn to provide maximum safety from falls.

7. Hand protection suitable to the hazard is to be used.

4.2 McNally Smoking Policy

There is to be absolutely no smoking in any company building, trailer or marine vessel. Smoking is to be kept to designated areas and away from all explosive materials. Smoking is not to take place in any confined space, tunnel, shaft or anywhere an explosive gas has the potential to exist.

4.3 Personal Cellphone Use

Personal cellphones are not to be used for any reason during company time. If a family member needs to get a hold of a worker during company hours they should call the site office number and someone will get the employee to the phone.

Personal cellphones may be used during lunch break however they must be used in a location where no moving vehicles or equipment are present.

Use of a personal cellphone during working hours or used where there is danger of moving vehicles and equipment is subject to disciplinary action.

4.4 Housekeeping

Good housekeeping means a tidy, clean, organized worksite. An organized worksite is one where things are arranged in some kind of logical order and consistently maintained. Poor housekeeping can quite often be the root cause for a lot of slips, trips, falls and other minor personal injuries. The following housekeeping rules are to be followed without exception on all worksites:

1. Work and travel areas will be kept tidy, well lit and ventilated.
2. Trash such as drinking cups, cans and scraps from lunch are to be properly disposed of.
3. Available material, equipment, concrete forms etc. are to be stacked in an orderly fashion away from walkways, doorways, ladders and stairways.
4. Materials piled, stacked or otherwise stored are to be prevented from tipping or collapsing.
5. Materials are to be stored away from overhead power lines.
6. Leads, hoses and extension cords shall be hung up with a non-conductive material, off all floors, stairways and walkways.
7. All walkways are to be kept free of debris and hazards including ice and snow.
8. Each trade is responsible for the general housekeeping in their respective work areas.
9. Where such items as protruding rebar and anchor bolts create an impalement hazard or tripping hazard, they shall be properly protected and conspicuously marked.
10. Trash barrels and 45-gallon drums shall not be hoisted by holes cut in the sides; adequate means of support shall be used i.e. lifting harness for barrels.
11. A current floor plan which identifies emergency exits is to be posted near an exit door in all workplaces.
12. Oil, grease and other such liquid spills shall be cleaned up at the time of spill and are not to be left unattended.
13. Lighting in the workplace are to be adequate for the task being completed. Lighting is to be maintained. When light bulbs have burnt out maintenance is to be informed immediately for the bulb(s) to be changed.

4.5 Sanitation and Hygiene

Detailed information on Hygiene can be located in the Construction Occupational Health and Safety Act Regulations in Sections 28 and 29.

Drinking water shall be provided at each workplace. Toilet and wash-up facilities will be available at each workplace (as required) and facilities shall be maintained in a clean and sanitary condition at all times.

Potential health hazards, in the form of chemical agents such as liquids, vapours, dusts, gases, fumes and mists, exist in many workplaces. These may enter the body through breathing, skin contact, swallowing etc. Depending upon amount and toxicity may affect different people in different ways.

Never take food or cigarettes into work areas. Toxic substances that settle on them could be swallowed. For the same reason, wash your hands before eating.

If you should suffer any unusual symptoms such as headaches, eye irritation or nausea, report immediately to your supervisor.

4.6 Physical Examinations

Physical examinations will be arranged for employees engaged in special operations (For example compressed air, hazardous soil excavation, modified duties etc.) as per Federal and/or Provincial requirements.

4.7 Common Office and Shop Hazards

The following is a brief description of common office safety & shop hazards that all employees should be made aware of. All employees should ensure that these common hazards do not develop into an accident or injury.

1. Be aware of the specific requirements, precautions and work area hazards that exist in the office & shop setting.
2. Know the location, and be familiar with the use of, all safety equipment including personal protective equipment, fire extinguishers, first-aid kits and eyewash stations.
3. Office & shop staff shall exercise caution when walking around blind corners or entering/exiting rooms or hallways. This is particularly important when carrying hot cups of coffee, trays or bulky items.
4. Office & shop staff shall proceed cautiously when walking up and down stairs or outside steps. Handrails will be used where provided.
5. Office & shop staff shall not store materials in an unstable manner.
6. Materials shall not be stored in electrical or utility rooms. This storage could result in reduced access to these rooms during emergencies or for regular equipment maintenance.
7. When lifting heavy or bulky objects obtain assistance or use a handcart.
8. Sharp instruments, such as knives, scissors, letter openers, etc should always be kept in the front of a desk drawer where they can be readily seen when the drawer is open.
9. Desk drawers and file cabinet drawers shall be kept closed when not in use.
10. To minimize overbalancing file cabinets office & shop staff should only open one of the upper filing cabinet drawers at a time.
11. Office & shop staff who become assigned field duties must observe the safety rules as applicable to the work site and if any office & shop staff are required to visit the field they shall wear appropriate personal protective equipment as required by that particular jobsite (could include hard hat, safety boots, safety glasses, safety vest or hearing protection).

12. A map of the work place that shows evacuation routes and head count location, as well as the location of emergency equipment, first aid station, fire sprinkles, alarm pulls and fire extinguishers must be posted at exit door.
5.0 SAFE PRACTICES AND PROCEDURES

This chapter includes Work Procedures and company policy for a diversity of areas within the company. Each topic has been placed on its own page or half page to allow for photocopying when copies of procedures of specific tasks are needed. As well, a revision key has been added after each provision to track changes and updates to ensure that procedures are updated at least once a year or more frequently if needed.

5.1 Attaching Cable Clips and Clamping
5.2 Boom Truck
5.3 Cleaning Solvents and Flammables
5.4 Compressed Gas

5.1 Attaching Cable Clips and Clamping

1. Wire the thimble to the rope at the desired point, then bend the rope around the thimble and secure temporarily by wiring the rope members together.

2. First attach the clip farthest from the thimble and tighten (be sure the base of the saddle rests upon the live end of the rope and the "U" bolts on the short end.) All clips must be attached in this manner.

3. The clip nearest the thimble goes on next. Do not tighten yet. If one or more additional clips are to be attached, place them at an equal distance apart between the clips already attached.

4. Before tightening, place some stress on the rope to take up the slack and equalize the tension on both sides of the clip. (Do not apply too much stress or the clip attached in step 1 will not hold). Tighten all clips.

5.2 Boom Truck

The importance of safe operation cannot be over emphasized. Carelessness and neglect on the part of operator, job supervisor and planners, rigging personnel, and job site personnel can result in their death or injury and costly damage to the boom truck or property.

Qualified personnel shall operate the Boom Truck, license for both truck & crane.

Procedure

The operator must not operate the Boom Truck when he is physically or mentally unfit.

The operator is responsible for all operations under his direct control. When there is doubt as to the safety of an operation, the operator has the authority to stop the operation and refuse to continue until the unsafe condition has been corrected. (ie/hydro wires, insufficient light, bad weather)

Before starting the engine or engaging the power takeoff, the operator is to make sure that:
1. All daily inspection and maintenance has been performed.
2. All controls are in the off position.
3. All personnel are in the clear.

The operator must not start crane movement unless a designated signal person is within his range of vision. The operator will obey an emergency stop signal at all times, no matter who gives it.

The operator is to perform the following operations before leaving the control station or the boom truck for any reason:

1. Land any load.
2. Lower the boom onto the boom rest if possible, otherwise, securely fasten the boom from movement by the wind or other outside forces.
3. Move all controls to the off position.
4. Park boom truck.
5. Apply the truck parking brakes and check the tires.
7. Lock door of truck cab.

5.3 Cleaning Solvents and Flammables

See Chapter 14: Hazardous Materials for more information on handling chemicals.

Cleaning solvents are used in the day-to-day construction work to clean tools and equipment. Special care must be taken to protect the worker from hazard that may be created from the use of these liquids. Wherever possible, solvents should be non-flammable and non-toxic.

The foreman must be aware of all solvents/flammables that are used on the job, and be sure that all workers who use these materials have been instructed in their proper use and any hazard they pose.

The following instructions or rules apply when solvents/flammables are used:

1. Use non-flammable solvents for general cleaning.
2. When flammable liquids are used, make sure that no hot work is permitted in the area.
3. Store flammables and solvents in special storage areas.
4. Check toxic hazard of all solvents before use. (MSDS)
5. Provide adequate ventilation where all solvents and flammables are being used.
6. Use goggles or face shields to protect the face and eyes from splashes or sprays.
7. Use rubber gloves to protect the hands.
8. Wear protective clothing to prevent contamination of workers' clothes.
9. When breathing hazards exist, use the appropriate respiratory protection.
10. Never leave solvents in open containers - return them to closed storage containers.
11. Ensure that proper containers are used for transportation, storage and field use of solvents/flammables.

12. Where solvents are controlled products, ensure all employees using or in the vicinity of use or storage are trained and certified in WHMIS and that all WHMIS requirements are met.

5.4 Compressed Gas

Always use care in handling all compressed gas cylinders. They must not be dropped, jarred or exposed to temperature extremes and should always have their contents properly identified.

Cylinders must have the valve cap or valve protection device in place at all times, except when in actual use or connected to a welding set. Cylinders are never to be rolled or lifted by the valve or valve cap. A suitable cradle is to be used for transporting.

Compressed gas cylinders, whether full or empty, are to be stored and transported in an upright position and secured so they cannot fall or be upset. They must be stored separate from fuel-gas cylinders or combustible materials (especially oil or grease) a minimum distance of 20 feet or by a 5-foot high non-combustible barrier. In addition these cylinders must not be placed within 5 feet of an electrical outlet or where they might become accidentally a part of an electric circuit.

Never force connections that do not fit and never tamper with the safety relief devices of cylinder valves.

Before the regulator is removed from a cylinder, the valve needs to be closed and all pressure released from the regulator. Never use a leaking cylinder. Take the leaking cylinder outdoors and store away from any ignition source, notify the supervisor and deal with the situation immediately.

The recessed top of cylinders is not a resting place for tools.

A training course must be taken before working with propane.

Oxygen:

Oil, grease or similar materials can not be allowed to come in contact with any valve, fitting, regulator or gauge of oxygen cylinders. Also, oxygen shall never be used as a substitute for compressed air.

When an oxygen cylinder is in use, the valve should be opened fully in order to prevent leakage around the valve stem.

Acetylene:

Acetylene cylinders are to be properly secured and always used, transported or stored in a vertical position. Cylinders shall be protected from sparks, flames and contact with energized electrical equipment.

An acetylene cylinder valve shall not be opened more than one and one-half turns of the spindle and preferably no more than three-fourths of a turn.

Employees shall not use acetylene in a free state at pressures higher than 15 psi.

All gas bottles must be stored outdoors.

Fire Extinguisher must be provided at each storage area.

5.4.1 Compressed Air (Work Procedures)

Scope
To reach the work face, workers must pass through a man lock that is to be compressed to the working pressure. When leaving the compressed air workplace, workers must be decompressed to normal atmosphere by a controlled decompression, or release of air.

Potential Hazards

Health Effects (Compression):

Air Space Equalization: Lack of clear body airways for equalization causes an imbalance of pressures in body areas. For example, the Eustachian Tubes must be clear to allow the pressures on either side of the eardrum to balance, failure to do so will cause acute earache and possibly a perforated eardrum.

Health Effects (Decompression):

All decompression must be strictly controlled for the time periods laid down by the Ministry of Labour's Decompression Tables. If decompression is not controlled, nitrogen bubbles are formed in the tissues. Formation of nitrogen bubbles will lead to decompression sickness. There are two (2) main types of decompression sickness.

1. **Type I**: Usually called the "bends", this is manifested by pain in one or more of the limbs. This may commence at any time up to twelve (12) hours after decompression. The pain may be slight or agonizing.

2. **Type II**: Affects the cardiovascular, respiratory and neurological systems. Occasionally, limb pains are present and usually appear early at the end of decompression or within forty-five (45) minutes of decompression and may show up as:
   - Tingling, weakness, numbness or paralysis in the limbs, collapse with signs of shock
   - Spots of flashes of light before the eye
   - Loss of balance or consciousness,
   - Cardiovascular problems
   - Abdominal pains, with or without vomiting
   - Disorientation, memory loss, malaise if the brain is affected.

Procedure

Compression, Decompression and Medical Locks

**TBM Air Lock**

Used to compress and decompress workers at the beginning and end of the work shift. The air lock is located forward on the TBM allowing access to the cutterhead or at the bottom of a shaft.

**Medical Lock**

Serves two (2) purposes:

- Medical testing of suitability of a worker to be exposed to compressed air.
- Therapeutic recompressions – this lock is located on the surface within close proximity to the shaft.

**Lock Tenders**

Lock-tenders for both the man lock and the medical lock will be competent people selected by the Project Superintendent to control the compression and decompression rates for the workers. Those chosen will be trained to understand the hazards associated with compression, decompression, decompression sickness and the importance of accurate record keeping. A lock-tender must ensure that the compression and decompression are accurate according to the established procedures.

If decanting rapid decompression to atmospheric pressure followed quickly by recompression in a separate chamber (e.g., medical lock) is conducted, the Project Physician must be notified.
In the event a worker collapses or becomes ill during decompression, the attendant must raise the pressure in the man lock to the equivalent pressure in the work chamber and immediately notify surface to alert the physician on call.

The medical lock attendant (who may also be the air lock attendant) will hold a current St. John Ambulance First aid Certificate with CPR and be familiar with the aspects of working in compressed air. He will work in harmony with the Project Physician with respect to handling the medical lock.

Treatment of Decompression Sickness:
The treatment for all forms of decompression sickness is recompression. A supply of clean air at a pressure of at least 0.7 bar above the maximum working pressure used in any work chamber on the project must be available to the medical lock on site. Oxygen therapy, if used, must be given under the supervision of a physician. Because Type II-Decompression sickness may be difficult to diagnose, it is essential that all workers, who develop abnormal signs or symptoms within 24 hours of being exposed to compressed air, should be urgently recompressed.

Working Pressure and Medical Requirements:
Where workers are employed at pressure up to 14 psi:

1. Decompression procedures should be followed using the appropriate tables.
2. Exposure to pressure should be limited to two (2) periods in any 24 hour period.
3. Each worker must spend at least 12 consecutive hours at atmospheric pressure in any 24 hour period because the state of super-saturation still exists at the end of a normal decompression. This means that the period in compressed air plus the time required for decompression (including the time taken to reduce pressure during stages) must never exceed 12 hours.
4. Workers must undergo a radiographic examination of major joints unless they have been x-rayed within the previous 5 years and the x-rays results are available.
5. Provide health education to workers on the health hazards of working in compressed air; i.e., decompression sickness and the necessary precautions including the medical fitness criteria (to be completed by Safety Department).

Construction Projects Regulation Requirements:
The Regulations for Construction Projects requires a constructor of a tunnel in which workers work in compressed air to employ at least one qualified medical practitioner preferably experienced in hyper baric medicine as project physician to conduct medical examinations and establish a medical treatment program for workers.

Duties of Project Physicians:
Be available to render immediate medical treatment or advice on the treatment of decompression sickness to workers working in compressed air.

Conduct medical examinations for workers before beginning work in compressed air which include a physical examination and clinical tests as required. Results of an air test in the medical lock if a worker has not previously worked in compressed air shall be reported to doctor.

Complete fitness record forms for the examined workers. Advise the employer on the fitness of examined workers without disclosing to the constructor and employer the records or results of the examination or tests. Notify the Chief Physician of the Ministry of Labour in writing whether a worker is unfit or fit with limitations to work in compressed air.

Maintain the medical records in a secure place for at least six (6) years from the last entry at which time it may be forwarded to the Chief Physician, or a Physician designated by the Chief Physician. In any event, the records must not be destroyed for a period of forty (40) years from the time such records were first made or twenty (20) years from the time the last of such records were made, whichever is greater.
Air Lock

The air lock is a two compartment pressure vessel specifically designed to compress and decompress personnel entering or leaving the cuttinghead of the TBM. The air lock consists of a primary lock and an ancillary lock. The primary lock is the chamber generally used for access and egress from the work chamber. The ancillary lock is generally used in an emergency.

The lock is designated to be operated by competent and trained personnel, who are experienced in operating air locks and are familiar with compression and decompression procedures as required by local codes and legislation. A competent and approved person must be designated Lock Tender. It shall be the lock-tender's responsibility to effect the safe operation of the lock.

Badge (for compressed air worker only)

Wear badge for 24-hours after working in compressed air.

Badge shall state the name of constructor, name and telephone number of Physician, location of medical lock at project and the words "compressed air worker".

In case of decompression sickness, take the sick worker immediately to a medical lock.

Buzzer, Bell System

An electric buzzer or bell system shall consist of a switch and buzzer or bell located:

1. in every work chamber near the door that leads to an air lock;
2. in every air lock;
3. near every lock tender's work position.

Code of Signals (post signs)

1 - signal – when no people are in the air lock, material is coming out;
3 - signals – people are coming out of the air lock.

Smoke Line

A smoke line shall be provided from each work chamber if an air lock or bulkhead is located between the chamber and the surface. The smoke line shall extend from face to ventilation system at back of gantry, for air lock on TBM.

Supervision Decompression Procedures

The rate of decompression required by the "Tables" may be doubled with respect to a worker if and while performing the work in compressed air, the worker:

1. has not been exposed to air pressure greater than 220 kilopascals;
2. has remained under compressed air for a maximum of 30 minutes;
3. has not done manual work.

5.5 Concrete Lining Forms for Tunnel (Work Procedure)

Scope

This procedure details the method of installing formwork for the construction of the secondary lining.

Potential Hazards

Feet slipping on curved surface when cleaning or placing concrete blocks for invert of forms.
Pinched fingers & feet when installing section of forms.
Oil spraying into eyes when oiling forms.
Workers may be struck by the traveller, when moving forms.
Chips of steel from bolts & nuts when using air gun to tighten bolts.

Procedure
1. In the initial set up of forms, invert section will be set up in bottom of shaft & braced
2. Traveller will be installed next, to move invert sections into tunnel
3. After all of the invert has been set & braced, sided top section will be installed
4. Invert section installed in shaft will be moved to front of forms
5. Top & side doors on forms will be opened; top & side bracing will be installed.
6. Bulk heads will be installed at end of forms & braced
7. Form vibrator & slick line will be installed as required
8. After first pour, side form & invert form will be stripped.
9. Invert form & one side & roof panel are moved to front of forms for placing
10. Concrete blocks or spuds are used to set invert forms.

5.6 Confined Space

Sections 60-62 in the Occupational Health and Safety Act outlines the government requirements for confined space entry.

5.6.1 Definition

A “Confined Space” means a space where entry or exit to/from the space is restricted and where a hazardous gas, vapour, dust, fume, or any oxygen-deficient atmosphere may occur because of its construction, location, contents or the work activity therein. This could include a storage tank, ballast tank, pump room, cofferdam or other enclosure. It could also be a hold or structure that is not designed or intended for human occupancy, except for the purpose of performing work and has:

- poor ventilation,
- the possibility of an oxygen deficient atmosphere, or
- the possibility of an airborne hazardous substance.

It is both the supervisor and the employee’s responsibility to ensure that safe working conditions for confined space entry are maintained. However, always assume that a hazard exists. It is the responsibility of any worker who must work in or around a confined space to follow this procedure.

Entry into a confined space shall be avoided if possible. Only employees properly trained on the hazards associated with confined space work shall be allowed to enter a confined space. Before entering a confined space, a confined space entry permit shall be obtained from the Constructor and posted. (See Table 16)
5.6.2 Hazards in Confined Space

Hazards encountered in a confined space can include the following:

- Oxygen deficiency or enrichment
- Toxic vapours of gases
- Temperature extremes
- Electricity (including static)
- Moving parts
- Slips and falls
- Hazardous chemicals
- Flammable liquids or gases
- Noise

Before any work is allowed in a confined space, it must be made safe for entry for the duration of the work. All existing and potential hazards must be eliminated. Smoking is not permitted in any confined space at any time.

<table>

</tr>
<tr>
<td>Utility Maintenance Holes</td>
<td>Accumulation of toxic and/or combustible fumes from ducts entering the chamber.</td>
</tr>
</tbody>
</table>

5.6.3 Confined Space Entry Permits

Confined space entries must be planned. Entry permits must be completed for all confined space work prior to entry. The Supervisor must keep a copy at the workplace and send one copy to the safety coordinator.

Permits must be obtained separately for each specific job, location, person and time. Permits must not be carried from one shift to the next. A copy of the permit is to be signed off by the employee in the confined space prior to entry and posted at the entrance point to the confined space.

Work permits are available in the Site Office, Head Office and in the Supervisor's Job Start Up Kit. These permits must be kept on file for a period of two (2) years.

5.6.4 Atmospheric Testing

Prior to entering a confined space, all levels of the confined space must be tested for the presence of flammable or toxic gases and vapours, an oxygen deficient atmosphere, carbon monoxide and for any other hazards. If flammable or toxic gases or vapours are detected or if an oxygen deficiency is found, forced ventilation shall be used to maintain oxygen at a safe level and to prevent a hazardous concentration of flammable or toxic gases and vapours by using a fan or compressed air.

The person doing the testing must be trained. Testing must be done prior to entry and while the worker is inside. No entry to the confined space is to be made when:

- Explosive readings are above zero
- Oxygen readings are less than 19.5% or more than 23.5%
- Toxic vapours or fumes are above the safe threshold limit values are present
Electric welding, gas welding, cutting or any other hot work shall not be performed on the interior, exterior or near the openings of any confined space which may contain flammable or explosive gases or vapours until the space has been properly purged. See also procedure for **Gas Testing in Chapter 5** of this Safety Program.

### 5.6.5 Ventilation

The confined space must be ventilated with fresh air prior to entry. Confined spaces are to be ventilated either by natural or mechanical means but the effectiveness of natural ventilation is often unreliable. After the confined space has been cleaned, purged and ventilated, the atmosphere shall be re-tested for oxygen level, combustibility and toxicity. If the test still shows positive for any hazard, further cleaning, purging and ventilation may be required.

More information on Ventilation can be found in Chapter 5 in this safety program.

### 5.6.6 Personal Protective Equipment (PPE)

Those working inside a confined space must wear proper protective equipment. This equipment varies with the work to be performed and the type of atmosphere present. The equipment may include an approved respiratory protection device, protective clothing, approved chemical goggles, hard hats, gloves and safety boots.

Where the atmosphere of a confined space cannot be guaranteed because oxygen readings are less than 19.5% toxic gases, or vapour fumes are present, self-contained breathing apparatus shall be worn during the complete duration of entry.

The approved self-contained breathing apparatus are:

- Self-contained Scott Air Pak – Pressure/Demand – 30 minute duration with alarm at 4 minutes of air remaining.
- Supplied air (High-pressure) – Pressure/Demand – approximately 6-hour duration with one person on 300 CF cylinder set at 750 PSI at the regulator.

Cylinders of oxygen or other gases **shall not be taken into confined spaces**. This does not apply to breathing equipment.

Protective clothing and respirator equipment shall not be used as substitutes of proper cleaning and job preparation.

Employees working in sewers should launder coveralls frequently. Rubberized cotton gloves provide good hand protection. In wet places, boots and rubber overshoes protect against dampness and infection.

### 5.6.7 Emergency and Rescue

Before any person enters a confined space there must be an observer outside the confined space. This observer must be trained in both confined space and artificial respiration. A lifeline and harness assembly must always physically connect the observer to the person inside and they are to be able to communicate with each other.

The free end of the lifeline attached to the harness should be secured outside the enclosed space. The lifeline should be under the control of the observer who will keep the person inside under observation at all times.

A portable emergency alarm should be within reach of the person attending the lifeline. If the inside worker fails to answer the observer or seems to be behaving strangely, or if the alarm sounds on the monitor in the space, the outside worker must shout loudly to the inside worker to get out. If there is no response, the outside worker should begin pulling the person out by the harness.
If for some reason, the person in the confined space is in trouble and is not attached to a harness, or is attached to a harness but is stuck, the outside worker must not go in to rescue. Whatever overcame the person in trouble is just as likely to overcome the person going in. The observer must summon help by using the portable alarm or by yelling for assistance. Rescue training is absolutely necessary.

A rescue team consisting generally of at least two persons – an observer and a rescuer, accomplishes emergency rescues from confined spaces. The observer is equipped with a means of summoning assistance and remains stationed near the entrance of the confined space. The rescuer equipped with suitable protective equipment goes into the space to recover the casualty. The rescue team must be capable of bringing out any worker affected and may therefore require block and tackle, safety harness, stretcher and rope.

5.6.8 Training and Supervision

McNally will ensure that the workforce has been trained and made aware of the following:

- Potential health hazards of working in confined spaces.
- Proper procedures and precautions required for entry.
- Pre-entry procedures such as lockouts, blanking of supply lines and atmospheric testing.
- Use, maintenance and limitations of protective equipment.
- Proper rescue and emergency procedures.

Contractors and subcontractors must ensure that McNally is notified prior to confined space entry and the person in charge of the work operation must ensure that the necessary protective clothing, equipment and devices are available and that the workers are properly trained in both their use and care.

5.6.9 Confined Space Openings

When covers are removed from confined spaces, a railing, temporary cover or other temporary barrier or tripod shall guard the opening. Safe access to the confined space shall be maintained at all times. If possible, all cords, hoses, leads, etc. shall be routed through an entrance other than the employee access into the confined space.

Before employees are allowed to enter a confined space, all electrical and mechanical energy sources that could affect the employees working in the space shall be physically rendered inoperative, locked out and tagged. If required, the space shall be drained, vented and cleaned.

5.6.10 Responsibilities

Standby Person:

The “Standby Person” is the individual designated to stay outside of the confined space to assist the individual in the confined space area. This person should be a valid/certified First Aider. Should have a system for signalling if an emergency.

The responsibilities of the “Standby Person” include the following:

1. To maintain verbal communication with the confined space worker at all times.
2. To ensure a means of emergency signal is available. Also ensure that a fire extinguisher, mechanical ventilation, emergency stretcher and SCBA are available if required for rescue. Mechanical ventilation is supplied to the confined space as required.
3. Ensure that means of retrieval is available for the confined space worker, in the event of an emergency.
4. Obtain and post at the entrance to the confined space the Confined Space Entry Permit from the supervisor, or have it available for inspection. Return permits to Supervisor at end of shift.
5. Secure free end of lifeline outside confined space in the event of an emergency to aid removal of injured confined space worker.

Confined Space Worker:
The "Confined Space Worker" is the individual going into the confined space and responsibilities include the following:

1. Wear full body harness with lifeline when wearing a respirator to rescue a person.
2. Wear other personal protective clothing and/or equipment required.
3. If a compressed gas is required in the confined space:
   - The bottles are to be mounted outside the space.
   - A leak test must be conducted on the equipment, torch and hoses, prior to entering.
   - When work is completed, request the standby person to close the cylinder valves, bleed hoses and torches at the gauges, if possible, and remove the equipment.
4. Ensure your equipment/tools are in good working condition prior to entry (e.g. good insulation on welding electrodes and grounding on tools and equipment).
5. Ensure a confined space permit is posted or available for inspection and that you have signed this permit.

Supervisor:
The following are the responsibilities for the Supervisor watching over the confined space entry:

1. Has the obligation to assess the potential danger involved in an operation and provide the suitable protective equipment to his/her area members. If guidance is required, please contact the safety department.
2. Ensure this procedure is complied with and provide his/her workers with the appropriate training.
3. All workers working in the confined space shall be educated in this procedure.

5.6.11 Emergency Procedure for Injured Confined Space Worker

Standby Person:
1. If worker reports headaches, dizziness, irritation or other ill effects then stop work and evacuate the confined space.
2. Sound air horn or other emergency alarm to alert supervisor.
3. Remove confined space worker and perform First aid or CPR, if required, until the ambulance arrives.
4. If rescue is required, then standby must get help. Person entering confined space to remove injured worker must wear SCBA equipment, body harness and lifeline.

Supervisor:
1. React to emergency alarm from standby. Assess the danger/injury and call safety department and emergency services, if required.
2. Ensure confined space worker and standby are safely out of confined space. Ensure CPR or First aid is administered until the ambulance arrives, if required.

5.7 Conveyor Belt Operation (Work Procedure)

Potential Hazards
Belt may overheat leading to an emission of toxic fumes from the components of the belt.
Toxic gases from the cuttings may be present as waste material is deposited onto the belt from the auger.
Pinch points exist at the drive, head, tail and tension pulleys.
Workers may be struck by material falling off the conveyor.
Worker may fall off moving conveyor or get caught on bracket holding equipment over top of conveyor.

Procedure
1. Hydrogen sulphide monitors will be placed at the discharge end of the auger to alert workers to the presence of a toxic level. To aid in the dilution of gases present, an adequate ventilation flow must be present.
2. No worker will ride the conveyor belt.
3. Before the belt is started up, an audible and visual alarm will alert the workers that the conveyor is about to operate. The control lever will have a lock out device to stop conveyor from moving when a person is on belt.
4. Fire extinguishers, 10 lbs ABC, will be readily available along the walkway of the conveyor.
5. Before any repairs, adjustments or maintenance is done, the conveyor shall be stopped and the prime mover de-energized, locked and tagged out.
6. To prevent material from falling on workers who may have to work below while the conveyor is operating guards will be in place under the conveyor at those locations.
7. To aid in the prevention of a worker becoming entangled in moving parts, any jewelry (rings, pendants, etc.) shall be removed. Workers with long hair (shoulder length or longer) whose duties require them to work in the area of the conveyor will tie their hair back or put it up in a hair net. Workers must ensure that there are no loose parts of their work clothes dangling that may become caught up in the moving parts.
8. Any work along the conveyor that requires the use of a shovel will require that the shovel does not have a hand grip, this is to allow the shovel to be pulled free from the hands in the event it becomes caught in a moving part.
9. Tripping hazards will be eliminated by maintaining a clear walkway along the conveyor.

5.8 Cranes, Derricks and Hoisting Equipment
1. Cranes and rigging shall comply with the requirements of Federal or Provincial Regulations for mobile cranes and tower cranes.
2. Only authorized persons shall be permitted in the cab or on the equipment. No person shall be permitted to ride the hook, sling or load of any hoisting equipment.
3. Only operators, qualified by knowledge, training and experience to avoid endangering workers, equipment or materials, shall operate cranes of any types in all workplace locations.
4. Operators shall not leave their positions at the controls of cranes, hoists, derricks or other lifting devices while the load is suspended.
5. Load limits as specified by the manufacturer shall not be exceeded under any circumstances. Operating and maintenance procedures as specified by the manufacturer shall be followed.

6. Before a lift is attempted, the lifting mechanism shall be level, firmly supported with the hoist line centred over the centre of gravity of the load to be lifted.

7. For the first lift of each day, the load shall be test-lifted and the brakes checked (load lifted several inches and then tested). Slings and bindings shall be checked and shall be readjusted as necessary to ensure safety and stability. One person designated to perform this task shall give signals to the equipment operator.

8. The operator shall obey a “Stop” signal given by anyone.

9. Hoist lines, ropes or wire cables shall not be guided by hand when standing within reach of the drum or sheave. Proper splicing or mechanical clamping of the tail section shall make wire rope loops. Wire rope clips shall not be used to form eyes in wire rope bridle or slings.

10. Operators of cranes, derricks, hoists and other hoisting equipment shall exercise extreme caution when in close proximity to energized lines or equipment. Distance maintained from energized lines shall not be less than required by Federal or Provincial Regulations.

11. Tag lines shall be used on all loads where a worker may be endangered by the rotation or uncontrolled motion of a load being hoisted by a crane or similar hoisting device, one or more guide ropes or tag lines shall be used to prevent the rotation or uncontrolled motion. These guide ropes or tag lines must not be removed from the load until the load is landed and there is no danger of it tipping, collapsing or rolling. (OHSA Reg. 179)

12. All spreader bars shall be tagged and marked with the rated capacity.

13. Equipment repairs or maintenance need must be recorded in Log Book, with copies going from the operator to foreman, to Office (with Time Sheets); to shop.

14. Shop foreman will review Log reports & inform equipment superintendent if major repairs to be done or that has been done to Equipment. A list of all Major repairs to Equipment will be entered into a Computer File.

15. NO modification to hoisting equipment will be done without first getting head office approval.

16. Modification does not include Maintenance or Repairs to equipment.

5.9 Diesel D-30 Pile Hammer

Conduct and record a Toolbox Talk before beginning this job so that everyone understands their duties.

1. Check the crane, crane cables, sheaves, blocks & safety hook to be sure all in good condition.

2. If working on land - make sure the crane is setting on a firm and level footing.

3. Check the diesel hammer and its sling for any defects.

4. Make certain that the diesel hammer has sufficient fuel and oil before start up.

5. Attach (2) two tag lines of sufficient size and length to the diesel hammer.
6. Make sure everyone is wearing the required P. P. E.
7. Make sure the hammer "trip" and fuel shutoffs are working properly.
8. Place pile helmet on top of pile. Check alignment of hammer and piles, pull trip rope, raise piston and start hammer. Leave trip device high enough so that it can't reset and catch piston. Follow pile with driving leads as pile is driven to refusal.

5.10 Drilling and Blasting on Water (Work Procedures)

1. Drilling is to be done from an approved barge, which will be secured in place by two approved spuds to minimize any movement of the barge.

2. Divers are utilized at the project start to view the basin floor after dredging to identify any abnormal conditions that may effect the drilling operations. Divers to be used for the first three blasts to check results and then periodically throughout the remainder of the project.

3. Casing will be seated into the bedrock using a secured shorter template pipe to provide directional stability. Casing direction will be checked with a bubble level and a pitch indicator. All holes are to be 90 vertical, continually checked until complete.

4. Drill pattern and hole depth to be established for each project. Drill guidelines are established prior to drilling using a template and a DGPS tracking system to pinpoint exact hole locations.

5. The holes will be loaded down through the casing using 5" M210 cartridges and double primed with Pentex boosters and non-electric detonators to provide a back up for ensuring detonation. After holes are loaded the casing will be pulled and the shock tubes will be floated to the surface for connection when the shot is ready to be hooked up. Tubing is attached to small brightly coloured floats for visibility and will be tied off away from the drilling operation.

6. If holes must be left loaded overnight the site will be monitored by security staff. As well, the project is in a well-lit area and the actual site is only accessible on water.

7. In unsuitable weather conditions, work will be suspended until conditions improve.

8. After a blast is fired, initiation testing of each shock tube will be conducted. Should a misfire occur, the site will be secured and a diver will be sent down to assess the situation. A plan of action will be determined based on each individual situation. As well, all steps required by the Blasting Regulations and the Safety Act and Regulations will be followed.

5.11 Electrical/Mechanical Hazards and Lock-out Procedures

Additional information on this topic can be found in the OHSA Construction Regulations in sections 181 to 195.

The purpose of this procedure is to establish the requirements for the isolation of electrical and mechanical energy sources. Isolation shall be used to ensure the health and safety of workers where the unexpected start up or release of stored or residual energy could cause injury.
5.11.1 Hazards (Electrical/Mechanical)

- Electrical Safety Standards – All electrical installations and equipment used will meet Canadian Standards Association and Federal/Provincial Regulations.
- Temporary panel boards must be securely mounted, protected from weather and water, accessible to workers and kept clear of obstructions. All temporary panels to have labels showing voltage and breaker designation.
- Use only fuses or breakers of the recommended amperage.
- Follow approved procedures for tagging and lockout.
- Do not use extension or tool cords that are defective or have been improperly repaired.
- Do not wire plugs into outlets as disconnecting will take too long in an emergency.
- Protect cords from traffic.
- Protect Bulbs with cages.
- Always use a ground fault circuit interrupter (GFCI) with any portable electric tool operated outdoors or in wet locations.
- Any shock or tingle, no matter how slight, means that the tool or equipment should be checked and repaired if necessary.
- Locate all underground and overhead services before starting work. Determine voltage of electrical utilities.
- With backhoes, cranes and similar equipment near power lines, use a signaller to warn the operator when any part of the equipment or load approaches the minimum allowable distances.

<table>
<thead>
<tr>
<th>Voltage Rating of Power Line</th>
<th>Minimum Distance</th>
</tr>
</thead>
<tbody>
<tr>
<td>750 to 150,000 volts</td>
<td>3 metres (10')</td>
</tr>
<tr>
<td>150,001 to 250,000 volts</td>
<td>4.5 metres (15')</td>
</tr>
<tr>
<td>Over 250,000 volts</td>
<td>6 metres (20')</td>
</tr>
</tbody>
</table>

- Before moving ladders, rolling scaffolds or elevating work platforms, always check for overhead wires. Death and injury can be caused by electrical contact with access equipment.
- Unbroken electrical contact: If you don’t know the voltage treat it as high.
- In some electrical accidents the injured or unconscious person remains in contact with the live wire or equipment. Rescue should only be attempted after power has been turned off.
- In some cases of low voltage, when power cannot be turned off, break contact if possible. Use a dry board, rubber hose or dry polypropylene rope to move either the injured person or the wire.
- **Warning:** Even with dry wood or rubber, touching the injured person can be dangerous. Give first aid only after the injured person is free of contact.
- Never put water on fires in live electrical equipment or wiring. Water is a conductor and increases the risk of flash, arc and electrocution.
- An electrical fire in a confined space can rapidly deplete oxygen and may release toxic fumes. If possible, switch off power. Avoid inhaling fumes and vacate the area at once. If necessary, breathe through a damp cloth and stay close to the floor.
• Use a Class C fire extinguisher, intended for electrical fires, this type employs a non-conductive extinguishing agent. An ABC fire extinguisher may also be used on an electrical fire. Report fires immediately.

• Wiring or equipment involved in a fire must not be used until a supervisor approves it.

5.11.2 Procedure

1. The supervisor involved in the electrical/mechanical work, determines where the isolation of electrical/mechanical source is required and is to notify all other supervision working in the vicinity of the systems requiring electrical or mechanical isolation and test and try to engage the equipment to confirm the isolation.

2. The supervisor will tag and lockout the disconnect device with a scissor-type device (if required), to allow for the multiple installation of locks for other trades.

3. All supervision of trades working on the isolated electrical/mechanical system will ensure that each of their workers install locks and tags for their protection. If the same work continues into the next shift the incoming crew is to follow the same procedure after the first crew has removed their locks.

4. Locks used for isolation will be individually keyed and numbered and are not be used for any other purpose. All locks and disconnects must have a “DANGER – DO NOT ENGERIZE OR OPERATE” tag securely attached.

5. Lockout procedure for mobile equipment including trucks is as follows:

• Mobile equipment should be parked on a firm level surface, if possible.
• All hydraulic attachments, such as blades and buckets, will either be placed on the ground, or properly braced against falling. Operator will set brakes, shut off engine and exit the cab taking the ignition key (if so equipped).
• Ignition key will be given to mechanic. Mechanic will shut off the master switch.
• Mechanic will place a lockout tag on an applicable part of the mobile equipment, i.e. the door handle or steering wheel.
• The mobile equipment will only be started either after the mechanic has performed the work or under the direct supervision of the mechanic.
• After the work has been finished the mechanic will remove the lockout.

5.12 Elevating Work Platforms

Workers using elevating work platforms will be trained in its safe and proper use.

These platforms will be equipped with proper guardrails.

The platforms are to be used to raise workers and light tools only, not materials beyond its rated capacity. Workers on the platform must be protected from falling at all times using a fall arrest protection attached to the platform.

The operator’s manual must be available at all times and no worker is permitted to use planks and/or ladders (step or otherwise) on the platform at any time.

5.13 Entry into Cutterhead Area (Work Procedure)

Entrance into this area takes into consideration the requirements of confined space entry and working under compressed air (if required). Potential Hazards for this job are:

- A worker may slip and suffer an injury.
- Toxic gas or explosive gas build-up can lead to death of worker(s).
- Workers may suffer decompression sickness.
- Material may fall on a worker.
- Cutterhead movement while worker in the cutterhead area.
- Worker may fall into semi-fluid spoil in lower part of plenum chamber.

Procedure

1. Before any worker enters the cutterhead area, air sampling will be conducted for methane, hydrogen sulphide, carbon monoxide and oxygen levels. These will be recorded.

2. To reduce the risk of a fall resulting in injury and assist in recovery, the worker(s) will wear fall arrest devices complete with full body harness. No less than two people will enter and/or work in the cutterhead area, person will be trained in first aid, artificial respiration and CPR.

3. Good verbal communications via telephone or another device must be present before any worker goes through the door of the air-lock leading to the cutting head.

4. All material, not hand held, must be securely fastened and rigid before being lowered or raised in the work area. Use of web slings and a cable puller are recommended. The movement of the machine will be under the control of the person actually in the "head" to do examination or repairs.

5. All workers must follow the compression and decompression procedures to reduce the possibility of decompression sickness.

6. Before putting compressed air on in the cutterhead chamber, flood doors should be closed.

7. Propane to be used instead of acetylene when using cutting torch in compressed air.

5.14 Equipment and Vehicles

Equipment will have regular maintenance completed by competent individuals.

For trucks and equipment circle checks are to be completed by the operator prior to use to ensure that they are in good working condition.

Safe operating instructions are to be posted in or near the equipment where applicable and the operators manual are to be in the equipment where applicable.

Where machine guards are required or in the best interest of the employees they are to be installed and utilized without exception.

Where a machine guard has been installed employees are not allowed to tamper with the guard or remove it.
Tampering or removing the guard without permission from management may result in immediate termination of employment.

Any problems/concerns with the way a piece of equipment is running or operating are to be reported immediately to the shop foremen or supervisor.

5.15 Erection of Pre-cast Segments (Work Procedure)

Scope

Segments will be transported to the TBM on segment cars attached to the muck cars. There will be two (2) segment cars per train. The Segment Hoist Operator will signal the locomotive to move slowly to the heading until the segment car contacts the bumper lock. The Segment handler must ensure the cars are locked in position and the locomotive will be stopped with brakes applied.

Potential Hazards

Workers may be struck or run over by the cars as the cars enter the gantry. Personnel could be entrapped between the cars and the gantry.

Procedure

1. All personnel will remain out of the gantry while the trains are entering the tail area. The Segment Hoist Operator will not signal the locomotive forward until he is assured no one is in the gantry.

2. The Locomotive Operator will give 3 blasts of his horn before entering the gantry, this is to serve as a warning. The first car, when heading to the face, will be equipped with a green flashing light to serve as a warning of the approaching train.

3. The Segment Hoist Operator, once assured the cars are in position, will activate the automatic turn table and rotate the segments 90 degrees. Once all segments have been rotated, the Hoist Operator will lift the segments with the hydraulic lift, and when at the highest point, signal the locomotive to retreat from the gantry. After the cars have cleared the gantry, the Hoist Operator will lower the segments back onto the cradle.

Potential Hazards

Workers can be caught between the segments and the lower carwalk in the segment moving area during rotation. Also, pinch points are located at front of every car where the manual turn table release is located. If the segments are moved ahead too quickly and too far, workers in the erector area may be struck by the segment.

Precautions

Workers must not be on the lower carwalk during rotation of the segments. No worker will be between the cars during rotation. The Hoist Operator will ensure all personnel are clear of the lower carwalk region before rotating the segments and signaling the train to exit.

Under the guidance of the Segment Handler, the Segment Hoist Operator will move individual segments as required to the landing pad of the erector arm.

Procedure

1. The Segment Handler and Hoist Operator must have visual communications. Proper hand signals are of prime importance.
2. Workers may get trapped if standing in front of the segment when being moved to the erector landing pad. While the segment is in motion, the handler will stand slightly behind the segment on the lower catwalk and move with it.

3. To prevent workers in the erector area from being struck, the Segment Handler will bring the segment to rest on the carriage in line with the bumper block (this will be indicated by a red paint line).

4. The lift/lock key must be completely engaged before the segment is moved.

5. Personal protective equipment must be worn.

6. After installation of the first segment of the ring, the erector arm will be under the control of the Lead TBM Miner. The erector arm will pick up each segment and move it into position for installation. This procedure will continue until the ring is “keyed”.

Potential Hazards

Activity in this area will be extremely high and congested.

“Blind” spots are evident from the erector arm control stations (there are 2 [1 upper and 1 lower]).

A worker can be struck by falling objects e.g., bolts, impact wrenches etc., or a segment not installed correctly may fall on the worker(s) below.

Installation crew will have to reach over guardrails on platforms. This may place them in an unbalanced position and increase the risk of falling.

A worker may be struck by the erector arm when being moved back to the landing pad.

Exposure to an eye injury is increased due to the construction of the concrete rings.

During bolt installation and moving into position, the concrete may chip.

Unclear communications may lead to unwarranted movement of the erector arm by one of the people at the control station.

Procedure

1. Only one operator will begin segment movement. The other operator will stand clear of the control panel while the erector arm is being moved.

2. The lead installation person will maintain good visual and hand communications with the erector arm controller (L or R).

3. The erector arm is not to be moved until the segment has been securely installed, the rams reapplied and the installation crew cleared from the area.

4. Impact wrenches are to be secured to prevent falling.

5. Eye protection must be worn.

6. To prevent accidental movement of the work platform, a flip type of cover will be placed over the levers once platform is in position.
5.16 Erection of Rib & Lagging (Work Procedure)

Scope
This procedure details the method of construction of a rib & lagging primary lining with a Tunnel Boring Machine.

Potential Hazards
Run over by lagging cars and load on cars may become unbalanced and tip.
Pinched fingers & slivers in hands when unloading & building lagging & ribs.
Lagging falling when building the ring.
Feet slipping on curved surface of lagging & tail of the Tunnel Boring Machine (TBM).
Using chain saw to cut or trim lagging.

Procedure
1. Tunnel lagging to be delivered to site in complete sets. Bundle will be packaged such that sufficient clearance beneath the TBM, trailing gear is maintained.
2. On site one set of ribs and a selection of packing pieces will be added to each bundle of lagging.
3. Sets will be loaded onto a flat car using the tunnel crane.
4. On arrival at the TBM the flat car will be disconnected to allow the muck boxes to move under the conveyor. During the mining cycle, the lagging will be unpacked and stacked ready for building, and the flat car will be reconnected to the train.
5. On completion of the mine cycle, the tail can will be cleaned out, the pushing ring will be retracted and two bottom sections of the ribs will be placed into the invert. To eliminate the ingress of fines, filter cloth will be installed behind the lagging as required.
6. Once the rib is in place the lagging will be slotted into the flanges of the rib. Lagging will be built up evenly on each side of the tunnel. The top section of rib will be erected with its expanding joint fully closed and the remainder of the lagging boards will be inserted.
7. Mining will then commence for the next set. During this mine cycle, the lagging is exposed behind the TBM, once clear of the tail can, the lining will be fully expanded using the rib expander, forcing the lagging against the excavated surfaces. In soft ground, little resistance may be experienced to the expansion; in this case the ribs will be expanded to their optimum diameter.
8. Once fully expanded, packing will be placed to close the expanded ring.

5.17 Excavation and Trenching Safety

All excavation and trenching work must be in full compliance with Federal and Provincial Regulation and shall be barricaded with the appropriate barrier tape and other protective devices as required.

Excavations 1.2 metres or deeper or less than 1.2 metres in unstable soil shall be properly sloped, braced, or shored to prevent cave-ins as per Federal and Provincial Regulations manual and shall have a ladder
for access into the excavation with no more than 7.5 metres of travel in any direction as per Federal and Provincial Regulations manual.

All excavated and available material shall be retained 1 metre or more from the edge of the excavation.

When entering an excavation that may be considered a hazardous environment, by site safety representatives, proper personal protective equipment must be worn.

5.18 Explosive/Powder – Actuated Fastening Tools

There are a number of tools utilizing an explosive charge in use throughout the construction industry to drive fastenings.

The manufacturers of these devices provide detailed instructions regarding their use and maintenance. These instructions, along with the legislation specifically set out for their use, shall be closely adhered to at all times.

The following general recommendations apply to all explosive/powder-actuated tools.

1. Only properly trained and qualified operators are to use this type of tool. The user shall possess proof of this training issued by the manufacturer, authorized dealer/distributor, or other competent source.
2. The tool must be CSA standard approved for Explosive Actuated Fastening Tools.
3. The tool should be loaded just prior to use with the correct load for the job anticipated. Tools should never be loaded and left to sit or be moved to an alternate work site after being loaded.
4. The tool should never be pointed at anyone, whether loaded or unloaded. Hands should be kept clear of the muzzle end at all times.
5. Explosive/powder actuated tools should always be stored in their proper lockable boxes.
6. Explosive/powder actuated tools must never be used in an explosive atmosphere.
7. When used, the tool must be held firmly and at right angles to the surface being driven into.
8. Eye protection must be worn by the operator. Where there is a danger of spalling, full-face protection must be worn. Hearing protection is also to be worn in confined areas.
9. To prevent free-flying studs, ensure that the material being driven into will not allow the stud to completely pass through it (i.e. glass block, hollow tile etc.)
10. Manufacturers’ recommendations should be consulted and followed whenever there is a doubt about the material being driven into, maintenance procedures, or load strength to be used.

5.19 Fall Protection and Guardrails

5.19.1 General Procedures

Fall arrest systems are required when a worker may fall 2.4 metres or greater or into operating machinery, water or other liquids, or onto other hazardous substances, objects or surfaces.
A fall arrest system consists of a full body harness, a shock absorbing lanyard or similar device, rope grab, lifeline and lifeline anchor that will not allow a worker to fall more than 0.6 Metres. All safety belts, full body harnesses and lanyards to meet Federal and/or Provincial regulation standards. Belts, harnesses and lanyards must carry a CSA label.

Lanyards must be 16 millimetres (5/8") diameter nylon or equivalent. Lanyards shall be attached to the D-ring on the harness by locking snap hook, a spliced loop and thimble, or a D-clip attached to a spliced loop and thimble.

All lifelines must be 16 millimetres (5/8") diameter polypropylene or equivalent and used by only one worker at a time. Lifelines must be free from any danger of chafing and free of cuts, abrasions and other defects. Lifelines should be long enough to reach the ground if they are not, then they must be knotted at the end, cable-clipped or otherwise provided with a positive stop, to prevent the lanyard or hich from running off the lifeline. To attach the lanyard of a safety belt or safety harness to a lifeline, use a mechanical rope grab that meets CSA Standard 2259.2. Lifelines clipped, or otherwise provided with a positive stop to keep the hitch from running off the end of the lifeline.

If a worker falls they are not to grab the hitch lanyard or lifeline, in order to work properly the hitch must come under a load. All fall arrest equipment subjected to impacts caused by a free fall or by testing shall be removed from service.

Prior to each use, employees shall visually inspect all fall arrest equipment for cuts, cracks, tears, abrasions, undue stretching, overall deterioration, mildew, operational defects, heat damage, acid or any other corrosion. Equipment showing any defect shall be withdrawn from service and clearly marked as damaged (if not destroyed and thrown out).

Employees must not use the fall arrest equipment until they have been properly trained. Foremen shall ensure fall protection is available and used as required for all employees under their responsibility.

Fall arrest equipment is to be stored in a cool, dry place not subjected to direct sunlight and it is not to be used for any other purpose than Fall Arrest.

Proper guardrails shall be installed on open sides of all areas, holes in the floor where the fall distance exceeds 2.4 metres. Guardrails will conform to Federal and/or Provincial regulations. Basic wood or wire rope guardrails will have a top rail, midrail and toeboard secured to vertical posts or supports.

5.19.2 Fitting a Body Harness

A poorly fitting harness may cause unnecessary injury, even when used correctly. Follow manufacturer's fitting instructions.

**Fitting**

1. Undo buckles, hold harness by front and rear Dee rings to ensure straps are untwisted.

2. Pass head through straps between Dee rings positioning smaller frontal Dee ring on the chest and allowing straps to drape behind the body. Ask fellow worker to check length of upper straps for correct Dee ring positions (see Dee ring adjustment procedure).

3. Standing erect, reach to back of thighs to locate ends of sub pelvic straps. Sub pelvic strap will not be the same colour as chest strap. Pull straps from both sides so webbing is snug under the buttocks. Sub pelvic strap buckles should just reach chest strap buckles. To adjust, move orange plastic strap keepers away from quick connect buckles. Connect chest strap to sub pelvic strap by threading quick connect bar through chest strap buckle. Repeat on other side.

4. Holding buckle, feed webbing to required length adjustment. Pull excess webbing snugly through keepers. Reach between legs and locate one leg strap. Pass leg strap around front of thigh and through adjuster buckle on front of hip as before.
5. Adjust buckles to a snug fit; do not over tighten. Slide plastic keepers against quick connect buckles or feed grommeted webbing through keeper loops.

**Dee Ring Adjustment Procedure**

1. Rear dorsal Dee Ring should be located between the shoulder blades. Frontal Dee ring should be located below the sternum. For most fittings the Dee rings should not require adjustment.

2. Holding plastic Dee ring plate with one hand pull Dee ring. Push three bar slider against plastic Dee ring plate. Holding Dee ring against plate, pull looped webbing on both sides through slots. Repeat procedure if more adjustment is required.

Once your harness has been adjusted according to the fitting instructions, have someone familiar with fitting procedure check adjustment of harness as outlined below. A loose or poorly fitting harness is unsafe.

**Harness Adjustment Check**

1. Check harness adjustment by looking at and touching all harness components. Check correct location of frontal and dorsal Dee rings.

2. Leg strap ends must be secured. Slide secondary plastic keepers towards end of strap and secure leg strap webbing on grommeted harness. *Loose ends are dangerous.* If necessary tuck loose ends behind webbing.

3. Plastic strap keepers must be placed firmly against quick connect buckles. Check webbing is flat against the body, particularly in the leg loops. Hanging in harness with twisted leg loops can compromise circulation. Check correct location of sub pelvic strap.

*Do NOT alter or adapt any portion of the harness in any way. Tampering with a harness could result in unnecessary injury or death.*

**Maintenance and Storage**

A harness must be stored, maintained and inspected properly. Failure to do so could result in harness failure.

1. To clean, wipe with a wet sponge. Use a mild soap if necessary. Do not use chemicals or detergents. Rinse off soap with clear water and hang to dry. Do not dry with heat.

2. Harnesses should be hung up by the rear Dorsal Dee Ring, or placed loosely in a container. Store in a clean, dry area free from excessive heat, sunlight, harmful fumes, corrosive agents or rodents. Harnesses can be marked for identification with marker pens only on extreme end of webbing straps.

3. Any repairs to your harness must be carried out by an approved servicing agent.

4. Following any fall incident (even a light one) your harness should be inspected by a qualified safety officer/engineer, who will decide if the harness is safe for further use or if it should be repaired or destroyed.

**5.20 Fire Protection Requirements**

Be aware of the specific requirements and work area hazards that exist in your work area. Know the location, and be familiar with the use of, all safety equipment including personal protective equipment, fire extinguishers, first-aid kits and eyewash stations.
Office & shop staff should be familiar with all routes of exit from the office & shop building. Each office & shop will have an evacuation plan in place with a defined muster area. Each office & shop will appoint a competent person whose responsibility is to ensure that all office and shop staff are evacuated to the muster station and accounted for once a fire is discovered. As the situation dictates the designated person will contact the appropriate authorities and give them the pertinent information i.e. location and severity of fire, information regarding injured or trapped staff.

Do not attempt to fight the fire unless it is minor and easily confined using a fire extinguisher. Do not return to the building until notified to do so by a member of the Fire Department.

5.20.1 Use of Fire Extinguishers

Good Housekeeping is essential in the prevention of fires. Fires can start anywhere and at any time. This is why it is important to know which fire extinguisher to use and how to use it.

Always keep fire extinguishers visible and easy to get at. Fire extinguishers have to be properly maintained to do the job. Where temperature is a factor, ensure that care is taken in selecting the right extinguisher.

Types of Fires

Class A:
These fires consist of wood, paper, rags, rubbish and other ordinary combustible materials.

Recommended Extinguishers
Water from a hose, pump type water can, or pressurized extinguisher, and soda acid extinguishers.

Fighting the Fire: Soak the fire completely - even the smoking embers.

Class B:
Flammable liquids, oil and grease

Recommended Extinguishers
ABC units, dry chemical, foam and carbon dioxide extinguishers.

Fighting the Fire: Start at the base of the fire and use a swinging motion from the left to right, always keeping the fire in front of you.

Class C:
Electrical equipment

Recommended Extinguishers
Carbon dioxide and dry chemical (ABC units) extinguishers.

Fighting the Fire: Use short bursts on the fire. When the electrical current is shut off on a Class C fire, it can become a Class A fire if the materials around the electrical fire are ignited.

5.21 FitzWright “Explorer” Immersion Suits

Donning Instructions
Remove Shoes and pull on as you would a pair of overalls, then pull hood over head and close zipper with a slow even pull. Remove gloves from arm pockets and don. Inflatable vest only after entering the water.

Care and Maintenance
DO NOT Dry Clean – Buoyant Material is closed cell neoprene. After use rinse with cool or lukewarm fresh water and allow to drip dry, do not store in high temperature area. Lubricate zipper with paraffin wax and store with zipper in open position. Glue tears with neoprene contact cement.

Operation of Inflator
1. Bring inflation hose to mouth
2. Push inflation valve in with teeth and blow
3. Release between breaths and continue until fully inflated.

Zipper on Suit
1. The zipper is water-gas-and-pressure tight. It is a heavy duty precision product with each tooth individually riveted in place. The only way it can be damaged is by faulty handling. Therefore it is important to keep it clean and lubricated.
2. Periodically clean the zipper with a soft brush, making sure to remove all dirt and sand from between the teeth.
3. Lubricate the zipper with beeswax after every use. Lubricate inside teeth as well as the external parts and then close and open zip to dislodge excess wax.
4. Transport with the zipper closed to prevent sand or grit lodging in the teeth.
5. Store suit with zipper open so the rubber will not take a compression set.
6. Caution! Always close the zipper slowly and smoothly. If at any time the zipper will not close, it is probably a foreign object in the teeth and it should be reopened and cleared.

5.22 Flammable and Combustible Liquids

“Danger No Smoking or Open Flames” signs shall be posted around all flammable and combustible liquid storage areas.

Tanks shall be vented with a pipe not less than 1.25 inch inside dia. And shall be 12 feet high from the adjacent ground level and shall be kept 20 feet from buildings.

At least one 20-pound Class B fire extinguisher shall be kept between 25 feet to 75 feet from tanks. All tanks shall be properly grounded and labelled with the contents and Owner’s name. All tanks are to be double walled or have a Spill Tray under them.

5.23 Forklift

When operating a forklift you must be trained. Training must be updated at a minimum every two years. Be aware of the specific precautions and work area hazards that exist.

Required personal protective equipment:

- Hard hat
- Safety boots
- Safety glasses - as applicable
• Hearing protection - where noise levels exceed 85 dB.

Check the condition of the forklift prior to use. If there is a problem have it repaired or replaced, tag the unit out of service so no one else uses it. Prior to beginning the lift the operator must ensure good working order of the unit. This will include brakes, tires, cylinders, lights, fluid levels, hoses, etc.

Do not lift more weight than the manufacturer’s weight rating with the equipment.

In the event that the operator does not have a clear line of sight, one employee will be designated as signal person to assist the operator. The signal person will use basic, mutually agreed upon hand signals to assist the operator and stand in such a position so that a clear view of the operator and the process to be performed is maintained.

There are two methods of lifting that may be employed. The first involves having the load positioned the forks. The second involves lifting apparatus that is attached to the forklift forks.

1. Load positioned on the forklift forks
   - Ensure that load is securely positioned. If necessary secure the load using either chain, rope or cable slings
   - Tip the forks back to more securely “cradle” the load while travelling.

2. Load involving lifting apparatus attached to the forklift forks
   - Position forks directly over the load so that the lifting direction is straight up, as opposed to lifting in a slanted direction. In the case of pulling, or towing, the cable will be in a slanted position.
   - Attach load utilizing the appropriate method i.e. slings into eye hooks, spreader bars, lifting rings, lift pins into dowel holes, etc.
   - Begin the lift and movement of the product.
   - Lift the load only high enough to complete the task.
   - Movement of the load will be done slowly.
   - Ensure that a clear pathway exists in the event that the load is dropped or begins to swing during the operation. This applies, firstly, to all individuals present, and, secondly, to associated property.
   - Upon completion of the move, the load will be lowered onto a stable surface.
   - Loads lowered onto a truck will be secured prior to leaving the site.

5.24 Fuel Handling Procedures

5.24.1 Responsibilities

It is the primary responsibility of the Supervisor to see that all fuel handling and dispensing is done in a safe and proper manner in accordance with this procedure.

5.24.2 Environmental Protection Procedures

The following procedures are intended to prevent a loss or escape of product and, in the event of a spill, to minimize the impact on the environment.

Delivery of Fuel to the site:
Delivery of fuel is to be in approved tank vehicles or mobile refuelling tanks. Delivery can be directly into equipment or into storage tanks. Tank vehicles are to be operated only by a competent person.

Dispensing of Fuel:

Someone must be present for all dispensing or transfer of fuel for the entire duration. The attendant is to be aware of proper fuel handling procedures. Transfer and dispensing of fuel is to be done utilizing pumping equipment, an approved hose and top-fill nozzle.

Absorbent pads are to be placed around the fuel inlet prior to dispensing as required. Ensure that a site-appropriate spill containment kit is readily available.

Unreeling of the fuel transfer hose and nozzle is to be done with the nozzle in the upright position. The nozzle is to be kept clear of the ground when it is returned to the reel or storage position.

Verify that that the proper connection of the fuel fill hose to the fill pipe of the tank vehicle, mobile refuelling tank or the equipment being filled and the fill valve are open.

Transfer of fuel is to be stopped prior to overflowing leaving room for expansion.

Operation of moving equipment in the area of a fuelling operation is to be temporarily suspended. Welding and/or burning operations within 3 metres will be stopped while fuelling is in progress.

Maintain regular inspections of fuel systems and their components for leakage, deterioration or damage, in accordance with construction regulations.

5.24.3 Additional Requirements for Marine Operations

Secure barge on which equipment is mounted, marine vessel or service barge to the work platform or wharf with proper marine lines. Prior to fuel transfer to mobile refuelling tank on barge, to marine vessel or to barge mounted equipment, establish direct communication between the tank vehicle operator or mobile fuelling attendant and the marine operator. This shall be maintained until fuelling is completed.

Where it is necessary to transfer a mobile fuelling tank from the wharf or work platform to a barge, or from one barge to another, the tank shall be engineered for lifting and equipped with proper lifting points and lifting tackle and the transfer shall be effected utilizing hoisting equipment in accordance with normal safety procedures. During marine fuelling operations, the attendant is to be particularly vigilant in scanning the water area adjacent to the fuelling operation for possible leaks or spills.

5.24.4 Spills

Preventative measures are the best means of avoiding accidental release of petroleum products for protecting our environment. In the event of an accidental release, the following will occur:

1. Appropriate spill response equipment is to be available for all phases of the project. The Spill response equipment that is to be available on site is to include:
   - A commercially available kit recommended for 40 gal. Spill which typically includes:
     - 10 No. - 3" dia. X 48" oil socks
     - No. - 3" dia. X 10' oil socks
     - 40 No. - 17" x 19" oil pads
     - 8 No. - 18" x 18" x 2" pillows
     - 10 No. - Disposable material containment Bags
     - 2 pair - Latex gloves
     - gal. Granular absorbent
     - Polyethylene salvage drum container (1 @ 55 gal. Capacity)
• For sites where fuel is dispensed only (no storage facility) a commercially available kit recommended for 10 gal. Spill which typically includes:
  • No. - 3" dia. X 48" oil socks
  • 25 No. - 17" x 19" oil pads
  • 2 No. - Disposable material containment Bags
  • 1 pair - Latex gloves
  • 1 gal. Granular absorbent
  • 1 No. PVC Bag container
• Where the site is within 30 metres of a waterway, the kit is to include absorbent boom supplies.

2. Cleanup action will follow the Hazardous Materials (Spill Procedures) (See section 6.9 of this policy and program)

3. All spills or suspected spills of petroleum products and other hazardous materials, on land or into the water, regardless of size, will be reported immediately to the Supervisor. The Supervisor will report the spill immediately to the Project Manager or Designate, who shall ensure notification of the appropriate Authorities.

5.24.5 Posting of Procedure

Procedures for fuel handling and instructions for spills are to be posted or available on site.

5.24.6 Storage of Fuel on Site

Where the circumstances require, fuel may be stored in an approved mobile refuelling tank. Storage of mobile fueling tanks when not in use is to be within an area where there is no exposure to damage by vehicular movement. The storage area is to be located away from drainage channels. All tank vehicles and mobile refuelling tanks are to be properly labelled in accordance with the Transportation of Dangerous Goods regulations. Approved fire extinguishers (Minimum rating of 4A, 60-B, or C) will be located near the fuel storage areas and smoking will not be permitted in the area of this storage facility. "No Smoking" signs are to be posted and maintained in good condition. No smoking is to be permitted during any fuelling operation. No "hot work" is to take place within 5 metres of a storage zone. In cases where fuel is being stored on site a copy of these procedures are to be posted or available on-site and the instructions are to be relayed to employees in a Tool Box Talk session.

5.25 Gas Testing

Gas detection instruments are potential life-saving devices and should be recognized as such. To ensure that this valuable piece of equipment is functioning properly a "bump test" should be completed either at the start of each day (if used continually each day) or prior to use (if only used occasionally). These instruments should be calibrated on a monthly basis to ensure that the sensors are at acceptable levels.

McNally currently uses 2 types of Gas Detection Monitors – all from Industrial Scientific. Employees are to be properly trained on the use of each unit prior to use.

5.25.1 Use of Gas Testers

Four steps to a successful Gas Detection Program:

1. Turn on instrument and check battery level
2. Zero the instrument (see procedure below)
3. Bump Test the instrument (see procedure below)
4. Clear the Peaks (see procedure below)

5.25.2 Zeroing the instrument
To zero the unit (both ITX and TMX412 are the same) do the following:
1. Turn instrument on by holding the “Mode” button on until the word “RELEASE” appears on the screen.
2. The unit will count itself down and then stop at the “Realtime display” should have at least 3 numbers reading on the display in various corners.
3. Press the “Mode” button 2 times
4. The machine will say “Zero” and press “E” to start – Press the “E” button and unit will zero
5. Wait and it will return to the “Realtime display”

5.25.3 “Bump Test”
The “Bump Test” or Functional Test is defined as a brief exposure of the monitor to a known concentration of gas(es) for the purpose of verifying sensor and alarm operation. It is not intended to be a measure of the accuracy of the instrument.
If the instrument fails the bump test it should have a full calibration done prior to use.

How to complete a bump test
A bump test is completed as follows:
1. Turn the instrument on and warm-up.
2. Apply test gas.
3. Allow sensors to respond to the test gas.
4. Verify proper alarm function (i.e./ lights and audible alarm)
5. Remove gas and allow the monitor to clear.
6. If any of the sensors fail to respond:
   a. Verify the gas cylinder has not emptied
   b. Verify regulator is turned on (if applicable)
   c. Verify tubing is in place and not clogged
   d. Verify sensor ports are not plugged (the grate portion of the testor on the TMX and ITX units)
   e. Remove the instrument from service and have it calibrated to verify operation.

5.25.4 Clearing Peaks
Clearing the peaks is similar to zeroing the instrument
1. Once instrument is on and at the “Realtime Display” press the “Mode” button 4 times.
2. Then press the “E” button to reset.
3. Machine will reset and return to the Realtime display.
5.25.5 Calibration

McNally Construction Inc. has purchased a docking station for calibrating instruments. Instruments must be returned to head office once per month to be docked and calibrated. If this is not feasible for a jobsite alternate arrangements will be made to ensure the instruments are calibrated on a monthly basis.

5.25.6 Repairs

When a gas tester is not working properly it **must** be returned to Head Office. **The only** person allowed to do any repairs or even open the instrument is the Health and Safety Coordinator, a certified Health and Safety Technician.

5.26 Grinding

Severe injury may occur if proper protective equipment is not used and properly maintained.

1. Check the tool rest for the correct distance from the abrasive wheel, maximum 1/8" or 3 mm.
2. Replace the grindstone when adjustment of the rest cannot provide 1/8" or 3 mm clearance.
3. If the wheel has been abused and ground to an angle or grooved, reface the wheel with the appropriate surfacing tool.
4. Protect your eyes with goggles or a face shield at all times when grinding.
5. Each time a grinding wheel is mounted, the maximum approved speed stamped on the wheel blander should be checked against the shaft rotation speed of the machine to ensure the safe peripheral speed is not exceeded. A grinding wheel must not be operated at peripheral speed exceeding the manufacturer’s recommendation.
6. The flanges supporting the grinding wheel should be a maximum of 1/3 the diameter of the wheel, and must fit the shaft rotating speed according to the manufacturer’s recommendation.
7. Bench grinders are designed for peripheral grinding. Do not grind on the side of the wheel.
8. Do not stand directly in front of grinding wheel when it is first started.

5.27 Grouting (Work Procedure)

When installing either liner plate or concrete segments in tunnel or shaft, a void exists between the back of the rings & the ground. To prevent any ground settlement and to maintain the shape of the ring, it is necessary to fill this void as soon as practical after the ring has been constructed. This backfill is done by grouting through segments of the rings themselves or through the threaded coupling on the liner plate.

**Potential Hazards**

Liner plate will buckle if too much pressure is applied.
Grout spraying between joints of liner plate or out of hose when disconnecting grout hose from valve on liner plate or concrete segment.
Coupling on grout hose may break causing hose & grout to spray.
Finger & arms can get caught in the mixing arms of the mixer or agitator; grout can splash into a worker’s eyes when mixing grout.
Procedures

1. A cementicious grout mix contains cement and water. Sand, flyash/bentonite, or other additives such as accelerators, anti-wash out etc., may be used as required.

2. Grout may be mixed on the job site or delivered in a concrete truck. Grout may be pumped from the surface or transported to the face in a agitator car & then into a grout pump.

3. At the end of the last mining shift or at any time where extended stoppage is expected all hoses and tubes will be fully flushed.

4. For segmental grouting it will be necessary to install a valve between the injection nozzle and the grout hole. If the grout holes do not have non return valves, a valve is required to enable hose disconnection.

5. On completion of grouting each ring, as well as cleaning hoses etc. any spillage will be cleaned.

5.28 Hand Tools and Power Tools

5.28.1 General Guidelines for Hand tools:

All tools, regardless of ownership, shall be approved by the supervisor and maintained in good condition. Tools are subject to inspection at any time. A foreman has the authority and responsibility to condemn unserviceable tools, regardless of ownership. Defective tools shall be tagged to prevent their use or they shall be removed from the job site.

Employees shall always use the proper tool for the job performed and only for the purposes for which they have been approved.

Tools shall not be thrown from place to place or from person to persons; tools that must be raised or lowered from one elevation to another shall be placed in tool buckets or firmly attached to hand lines. Tools shall never be placed unsecured on elevated places and they must not be left lying around where they may cause a person to trip or stumble. Tools with sharp edges shall be stored and handled so that they will not cause injury or damage. They shall not be carried in pockets.

When working on or above open grating, a canvas or other suitable covering shall be used to cover the grating to prevent tools or parts from dropping to a lower level where others are present or the danger area shall be barricaded or guarded.

Pipe shall not be used to extend a wrench handle for added leverage unless the wrench was designed for such use.

Wooden handles that are loose, cracked or splintered shall be replaced. The handle shall not be taped or lashed with wire.

All cutting tools such as saws, wood chisels, drawknives or axes shall be kept in suitable guards or in special compartments.

Impact tools such as chisels, punches, drift pins, etc. become mushroomed or cracked, and they shall be dressed, repaired or replaced before further use.

Chisels, drills, punches, ground rods and pipes shall be held with suitable holders or tongs (not with the hands) while being struck by another employee.

Hammers with metal handles, screw drivers, knives with metal continuing through the handle and metallic measuring tapes shall not be used on or near energized electrical circuits or equipment.
The insulation on hand tools shall not be depended upon to protect users from shock. The non-current carrying metal parts of portable electric tools such as drills, saws and grinders shall be effectively grounded when connected to a power source unless:

- The tool is an approved double-insulated type
- The tool is connected to the power supply by means of an isolating transformer or another isolated power supply.

5.28.2 Power Tools:

All power tools shall be examined prior to use to ensure general serviceability and the presence of all applicable safety devices. The electric cord and electric components shall be given an especially thorough examination. Power tools shall be used only within their capability and shall be operated in accordance with the instructions of the manufacturer.

All tools shall be kept in good repair and shall be disconnected from the power source while repairs are being made. Electrical tools shall not be used where there is a hazard of flammable vapours, gases or dust. All power tools and cord sets shall be protected by ground fault circuit interrupter.

Pneumatic tools shall never be pointed at another person. Pneumatic power tools shall be secured to the hose or whip by some positive means to prevent the tool from becoming accidentally disconnected. Safety clips or retainers shall be securely installed and maintained on pneumatic impact (percussion) tools to prevent attachments from being accidentally expelled.

5.28.3 Defective Tools

Defective tools can cause serious and painful injuries. If a tool is defective in some way, DON'T USE IT. Obtain a tag from the office and tag and defective tool “Out of Service”.

Be aware of problems like:

- chisels and wedges with mushroomed heads
- split or cracked handles
- chipped or broken drill bits
- wrenches with worn out jaws
- tools which are not complete, such as files without handles

To ensure safe use of hand tools, remember:

- never use a defective tool;
- double check all tools prior to use; and
- ensure defective tools are repaired

Air, gasoline or electric power tools, require skill and complete attention on the part of the user even when they are in good condition. Don't use power tools when they are defective in any way.

Watch for problems like:

- broken or inoperative guards,
- insufficient of improper grounding due to damage on double insulated tools,
- no ground wire (on plug) of cords of standard tools,
- the on/off switch not in good working order,
- tool blade is cracked,
- the wrong grinder wheel is being used, or
5.29 Heavy Equipment

5.29.1 Getting on and Off Heavy Equipment

1. Clean mud off boots before climbing onto the machine.
2. Use the machines side grab rails and steps.
3. Face the machine and step onto the first step.
4. Maintain three-point contact at all times. Two hands and one foot or two feet and one hand.
5. Climb into the operator’s cab.
6. Before getting off the machine, make sure the machine is dogged out and further movement is prevented. Shut off machine if necessary.
7. Step out of the operator’s cab, onto the ladder and while facing the machine, descend using the three-point method.

5.30 Hoisting and Rigging

5.30.1 Rigging Equipment and Devices

All rigging equipment shall be thoroughly inspected by a competent worker prior to each shift and then as often as necessary during the shift to ensure safety. Damaged or defective slings shall be immediately removed from service. Hoisting and rigging shall conform to Federal, Provincial (State) Regulations. All rigging devices including slings shall be permanently affixed with identification stating size, grade and rated capacity.

Rigging not in use shall be removed from the immediate work area.

Rigging, including slings shall be hung on a rigging frame or otherwise stored in such a fashion to prevent bends and kinks.

Rigging equipment shall not be loaded more than its recommended safe working load as listed by the manufacturer.

Makeshift lifting devices formed from bolts, rods or reinforcing steel shall not be used.

5.30.2 Slings

Wire rope slings shall be lubricated as necessary during use. Slings shall be lubricated no less than every four months when in storage.

Slings shall not be left lying on the ground or otherwise exposed to dirt and the elements.

Eyes in wire rope bridles, slings or bull wires shall not be formed by wire clips or knots.
Protruding ends of strands, in splices on slings or bridles shall be covered or blunted.

Slings shall not be shortened with knots, bolts or other makeshift devices. Slings shall be securely attached to the load by the use of hooks with retaining devices or the use of shackles or other positive latching devices. Slings shall be padded or protected from the sharp edges of their loads and shall not be pulled from under a load when the load is resting on the sling. Slings shall be long enough to provide the maximum practical angle between the sling leg and the horizontal plane of the load.

Slings used in a basket hitch shall have the load balanced to prevent slippage.

Shackle pins shall never be replaced with bolts or other non-approved devices.

Only hooks with approved retaining devices shall be used. Hooks shall never be rigged so that they are point loaded at the tip of the hook unless they are designed for that purpose. The load shall be securely seated in the saddle of the hook. When eyebolts are used, care shall be taken to ensure the bolt is not side loaded.

Chain falls, come-alongs and other such devices shall not be loaded beyond their rated capacities and shall always be rigged for a straight pull.

The chain or hoist cable for chain falls, come-alongs or other such devices shall not be wrapped around a load and used in place of a sling unless specifically designed for that purpose.

Wire rope slings shall be removed from service when there is/are:

- Six (6) randomly distributed broken wires in one rope lay or three broken wires in one strand in one rope lay.
- Wear or scraping of one-third the original diameter of outside individual wires.
- Kinking, crushing, bird-caging or similar damage resulting in distortion.
- End attachments cracked, deformed or worn.
- Exposure to temperature in excess of 180°F (82°C) for fibre-core or 400°F (204°C) for non-fibre core.
- Corrosion of the rope or end attachments.

Natural and synthetic fibre rope slings shall be removed from service when:

- Abnormal wear is observed.
- Powdered fibres are found between strands.
- Fibres are cut or broken.
- There are variations in the size or roundness of strands.
- There is discoloration or rotting.
- There is distortion of sling hardware.
- Exposed to temperatures in excess of 180°F (82°C).

Synthetic web slings shall be removed from service when:

- Subjected to acid or caustic burns.
- Melting or charring of any part of the sling surface.
- Snags, punctures, tears or cuts are observed.
- Stitches are worn or broken.
- Fittings are distorted.
- Exposed to temperatures in excess of 180°F (82°C) for synthetic and at 200°F (93°C) for polypropylene web.

5.32 Hydro Wires

Extreme caution must be used when working around overhead wires.

5.32.1 Safety Precautions for working around Overhead Power Lines

- Locate and identify all overhead power lines, determine voltage before construction begins
- Have lines moved, insulated, or de-energized, contact the local utility for this
- Use a signaler whenever a backhoe, crane or similar device is closer than one boom length to a live power line of 750 volts or more
- The signaler must warn the operator when any part of the machine or its load approaches the minimum distance allowed in the construction regulation

<table>
<thead>
<tr>
<th>Voltage Rating</th>
<th>Minimum Distance</th>
</tr>
</thead>
<tbody>
<tr>
<td>750-150,000 volts</td>
<td>3 metres</td>
</tr>
<tr>
<td>151,000 – 250,000 volts</td>
<td>4.5 metres</td>
</tr>
<tr>
<td>Over 250,000 volts</td>
<td>6 metres</td>
</tr>
</tbody>
</table>

- Never use aluminum or metal-reinforced ladders near overhead lines or live electrical equipment or wiring. Even contact with a wooden ladder can be fatal under wet conditions.
- Never store material or equipment under overhead power lines if current is more than 750 volts and cranes or similar lifting devices will be involved.
- Where material or equipment must be stored under power lines, hang warning flags so that personnel will not use hoisting and lifting equipment
- Remember that overhead lines can be struck not only by booms and ladders but also by long pieces of material being lifted by hand, such as pipe.
- Be aware of wind swaying power lines into contact with equipment, hoist lines, or loads and be aware of wind blowing hoist lines or loads into contact with power lines.
- For Procedures on what to do should equipment make contact with Overhead wires see Emergency Procedures section in this Policy and Program.

5.33 Ladders

5.33.1 Portable Ladders

Ladders can be used safely if they are given the respect they deserve. Before using any ladder, make sure that it is in good condition and is the right ladder for the job to be done.

1. A single section ladder shall not exceed thirty feet in length.
2. An extension ladder shall not exceed sixty feet in length.
3. A ladder shall not be used when it has a broken or loose member or other fault.
4. A ladder shall have rungs evenly spaced at not more than twelve inches on centres.
5. A ladder shall have side rails not less than sixteen inches apart.
6. Ladders shall not be spliced together to provide long sections.
7. The minimum overlap on an extension ladder should be one (1) metre unless the manufacturer specifies the overlap.
8. Don’t overreach while on a ladder. It is easier and safer to climb down and move the ladder over a few feet to a new position. Always face the ladder when using it. Grip it firmly and use the three point contact method when moving up or down.
9. Ladders shall not be placed in front of doors opening toward the ladder unless the door is blocked open.
10. Ladders shall not be used in any horizontal position such as a platform, runway or scaffold.

5.33.2 Step Ladders

As with all ladders, make sure that the stepladder is in good condition, and is the right ladder for the job to be done.

1. Stepladders are to be used only on clean and even surfaces and no work is to be done from the top two steps of a stepladder, counting the top platform as a rung.
2. When in the open position ready for use, the incline of the front step section shall be one (1) horizontal to six (6) vertical.
3. The stepladder is only to be used in the fully opened position with the spreader bars locked.
4. Tops of stepladders are not to be used as a support for scaffolds.
5. Only CSA Standard ladders will be used.

5.34 Material Handling

An employee shall obtain assistance in lifting heavy objects or power equipment shall be used. Back belts or back braces shall be used as required.

When two or more persons are carrying a heavy object that is to be lowered or dropped, there shall be a prearranged signal for releasing the loads and if possible, everyone should face the direction in which the object is being carried.
The right way to lift is easiest and safest. Crouch or squat with the feet close to the object to be lifted, secure good footing, take a firm grip, bend the knees, keep the back vertical and lift by bending at the knees and using the leg and thigh muscles. Employees shall not attempt to lift beyond their capacity. Caution shall be taken when lifting or pulling in an awkward position. Employees should avoid twisting or excessive bending when lifting or setting down loads. When moving a load horizontally, employees should push the load rather than pull it.

When performing a task that requires repetitive lifting, the load should be positioned to limit bending and twisting. The use of lift tables, pallets and mechanical devices should be considered.

When using such tools as screwdrivers and wrenches, employees should avoid using their waist in a bent (flexed), extended or twisted position for long periods of time. Employees should maintain their wrists in a neutral (straight) position.

When gripping, grasping or lifting an object such as a pipe or board, the whole hand and all the fingers should be used. Gripping, grasping and lifting with just the thumb and index finger should be avoided.

When handling hazardous material proper personal protective equipment must be worn.

5.34.1 Manual Lifting

1. Size up the load. If you think you need help, ask for it.
2. Get a good footing.
3. Bend your knees, get a good grip on the object to be lifted.
4. Keep your back straight, lift with your legs and keep the object being lifted close to your body.
5. Keep your balance and do not twist or turn as you lift.
6. To put the object down again, do not bend from the waist. Keep your back straight and bend your knees, keeping the object close to your body until it is placed in a secure position.

5.35 Moving (not hoisting) Steel Beams

Because of the many varied sizes, weights and site conditions, it is very important that each operation be observed for its own obvious hazards.

1. Discuss the proposed work with all employees who will be involved.
2. If there are any other workers in the immediate area, advise them of your work.
3. Determine the size, length and weight of the beams to be moved.
4. Check that your slings, chains and hooks are of adequate size and in good condition.
5. Check the beams for any obvious projections that may cause a problem.
6. Check the area for debris, electrical wires, buried cable, vehicles, etc.
7. Designate one person to be the signalman for the machine operator.
8. The signalman is to make sure that all others are "out of harms way" before signalling the machine operator to proceed.
9. The machine operator will pull the beams at a slow speed.
10. Always keep observers well away from the work area.
5.36 Personal Floatation Devices

Immersion in cold water is a hazard for anyone who participates in activities on oceans, lakes and rivers, etc. The survival time in these waters is primarily dependent on the water's temperature and the insulating protection available.

Body size and build are significant physiological variables affecting cooling rates. Protective clothing such as an immersion suit help to minimize heat transfer and loss to the water. These suits can contribute and provide considerably more survival time than normal clothing.

Marine survival products are made from high tech materials to provide comfort, durability and protection. To ensure maximum performance, however, they must be maintained, cleaned and inspected on a regular basis. The procedures outlined below are a simple way to ensure consistent performance.

INSPECTION:
Before each use, inspect the following on your personal flotation device:
1. Seams for separating, tearing or fraying.
2. Shoulder and sleeve areas for separation or slippage of foam interliners.
3. Zippers for ease of movement and overall condition.
4. Snaps, buckles and tug-sites are in good condition.

TESTING:
Test your PFD at the start of each job for buoyancy. Products that are not in proper condition must be replaced.

SUNLIGHT:
To avoid premature aging of the nylon shell and stitching, PFD's should not be hung in direct sunlight for extended periods of time.

DRYING:
Unless your PFD is properly dried, you will encounter dampness and mildew. To avoid mildew, hang-dry after each use in a well-ventilated area away from direct sunlight. Do not stow PFD's while drying.

WASHING INSTRUCTIONS:
Personal flotation devices should be hand washed using a mild soap or detergent. Rinse thoroughly in clean water. Hang-dry in a well-ventilated area and out of direct sunlight. Do not dry clean or tumble dry.

5.37 Personal Protective Equipment

1. All workers, visitors and delivery personnel shall wear hard hats on all construction sites. Hard hats shall meet Federal and Provincial regulations.
2. Respiratory protection shall be worn as circumstances warrant. Employee to see supervisor for type of respirator required.
3. Eye protection shall be worn as required to reduce the risk of eye injury. Specific classes of eye protectors shall be matched to specific hazards.

4. Hearing protection to be worn as required.

5. Foot protection shall meet Federal and/or Provincial regulations and must be worn by all workers, visitors and delivery personnel as required.

6. Fall Arrest Systems to be worn to provide maximum safety from falls. For additional information refer to the Fall Protection and Guardrails section of this Health and Safety Policy and Program.

7. Hand protection suitable to the hazard shall be used.

8. All workers are to complete Table 2 “Materials Issue Form” for personal protective equipment.

5.38 Placing Concrete with Concrete Pump & Slick Line

This is a procedure for placing concrete in tunnel forms using a concrete pump & steel slick line with Victaulic couplings.

Potential Hazards
1. Finger & arm caught in agitator paddle in hopper of concrete pump.
2. Finger being cut off in swash valve of concrete pump.
3. Concrete sprayed into eyes.
4. Victaulic coupling coming apart when pumping concrete.
5. Concrete vibrator falling off forms & hitting a worker.
6. Concrete dripping through joints of forms onto bare skin causing burns.
7. Placing concrete too fast causing forms to shift due to improper bracing.
8. Being struck by rabbit or slick line when cleaning out line.

Procedures
1. Set up slick line from surface down shaft or alignment hole.
2. For vertical drop pipes, secure pipes by welding joints together or otherwise secure pipe so that pipe will not fall down shaft or alignment hole and hit a worker.
3. Run slick line along bottom of tunnel, to tunnel forms.
4. Connect slick line to pumping ports on top of concrete forms.
5. When concrete forms are filled to door level that you are pumping through, close doors & move to next door down the line.
6. A phone system must be established between concrete pump, bottom of drop pipe, and forms in tunnel.
7. When forms are full a rabbit is pushed through the slick line to clean out the concrete using either air or water. Extreme caution should be observed when performing this operation.
Clear warning to be given to all personnel within the vicinity of the forms before commencing clean out. All personnel should be moved clear of the open end of the slick line.

5.39 Portable Grinders

Abrasive wheels can cause severe injury. Proper storage of wheels, proper use of wheels and proper maintenance of wheels must be observed.

1. Familiarize yourself with the grinder operation before commencing work.
2. Ensure proper guards are in place and that safety glasses, face shields, gloves and safety boots are worn when using portable grinders.
3. Never exceed the maximum wheel speed (every wheel is marked). Check the speed marked on the wheel and compare it to the speed on the grinder.
4. When mounting the wheels, check them for cracks and defects, ensure that the mounting flanges are clean and the mounting blotters are used. Do not overtighten the mounting nut.
5. Before grinding, run newly mounted wheels at operating speed to check for vibrations.
6. Do not use grinders near flammable materials.
7. Never use the grinder for jobs for which it is not designed, such as cutting.

5.40 Powered Saws

5.40.1 Use of Chain Saws

Chain saws are used for many jobs in construction. Since this tool was primarily meant for use in the logging industry, it can be an unfamiliar tool to some workers. Workers must be trained in its safe use before using a chain saw. This training must include a minimum of the following elements:

1. The proper personal protective equipment to be worn is set out by the manufacturer and Occupational Health & Safety Legislation.
2. Fuelling of the saw must be done in a well-ventilated area and not while the saw is running or hot.
3. An approved safety container must be used to contain the fuel used along with a proper spout or funnel for pouring.
4. The correct methods of starting, holding, carrying, or storage and use of the saw as directed by the manufacturer must be used.
5. Ensure that the chain brake is functioning properly and adequately stops the chain.
6. The chain must be sharp, have the correct tension, and be adequately lubricated.
7. When carrying/transporting a chain saw the bar guard must be in place, the chain bar must be toward the back and the motor must be shut off.
8. The chain saw must not be used for cutting above shoulder height.

5.40.2 Use of Hand-Held Power Circular Saws

This type of power hand tool is one of the most commonly used in construction. Because of this common use there are numerous accidents due to thoughtless acts. The following are the minimum accepted practices to be used with this saw:

1. Approved safety equipment such as safety glasses or face shields are to be worn.
2. Where harmful vapours or dusts are created, approved breathing protection is to be used.
3. The proper sharp blade designed for the work to be done must be selected and used.
4. The power supply must be disconnected before making any adjustments to the saw or changing the blade.
5. Before the saw is set down be sure the retracting guard has fully returned to its down position.
6. Both hands must be used to hold the saw while ripping.
7. Maintenance is to be done according to the manufacturer’s specifications.
8. Ensure all cords are clear of the cutting area before starting to cut.
9. Before cutting, check the stock for foreign objects or any other obstruction, which could cause the saw to “kick back”.
10. When ripping, make sure the stock is held securely in place. Use a wedge to keep the stock from closing and causing the saw to bind.

5.41 Propane

Since propane is heavier than air and invisible, it is a special concern when it is used on the job-site.

All installations and use of this product on the job-site must comply with the Government Legislation set out for its safe use. Additional information concerning the handling and storage of propane can be located in the Construction OHS A Regs 42, 43 and 122.

5.41.1 Propane Cylinder Storage & Handling

Propane is non-toxic but can displace air leading to dizziness, weakness and death, when working with propane workers must ensure adequate ventilation. Propane will flow into ditches and settle close to the ground. Propane vapour is 1.5 times heavier than air and propane liquid is about half the weight of water. Propane will only burn at certain mixtures. Combustion will not occur when there is too much or not enough fuel.

When working around propane open flames and cigarettes are NOT allowed.

Procedure

1. Storage of cylinders is to be outdoors away from doorways, confined spaces and building openings or in an approved storage area/cylinder room. Storage areas should be on firm, even ground.
2. Propane storage areas must be identified with proper signage. Proper signage should include “Propane”, “No Smoking” or “No source of Ignition within 3 meters”.
3. Propane is not to be stored with oxidizing agents, oxygen and chloride cylinders. (As per MSDS)

4. Cylinders must be stored upright/vertically and secured to avoid tipping over. While in use propane bottles are to be securely held in an upright position.

5. Ensure that all valves are tightly closed when being stored or transported.

6. When removing or replacing a cylinder in the storage area, place carefully and do not throw cylinders.

7. Do not drag, roll or drop cylinders as this could cause damage.

8. When lifting cylinders follow proper lifting, carrying and mounting procedures as the cylinders are heavy when full and lifting techniques are to be used to avoid back injuries.

9. Carry only 1 cylinder at a time regardless of whether they are full or empty.

10. When transporting cylinders ensure they are properly secured and that they are transported upright/vertically. Do not transport in the cab of truck or on passenger seat. If cylinder must be transported in a vehicle ensure that it is upright, secure and the vehicle is well ventilated.

11. Never lift a cylinder by using the valve guard or the valve. A proper carrier constructed for the purpose of lifting propane and compressed gas cylinders is the only acceptable means of lifting propane tanks via crane etc.

12. Tank valves and regulators are to be removed from the tank prior to any movement of the tank.

13. Crane hooks shall be equipped with a "safety latch".

14. All trucks, cranes or equipment used to handle propane tanks must be equipped with a fire extinguisher appropriate for the size and type of tank being handled.

15. Except in an emergency, any movement or repositioning of tanks shall be performed by a competent worker.

16. Tanks are not to be heated to increase flow.

17. Tanks are not to be hooked up and used without proper regulators.

5.41.2 Propane Heaters and Torches

Propane must only be used in a well ventilated area and no closer than 3 meters from any source of ignition, when using propane equipment a fire extinguisher must be kept near by.

Location of propane heaters are only allowed in an area of a building that is under construction, where there are only construction people in the area, must be kept away from combustible materials and on a level, solid ground.

Procedure for Connection of Heater Hose to cylinder

1. Wear gloves and eye protection

2. Use Regulator

3. Place heater at least 15ft from the cylinder

4. Face heater away from the cylinder

5. Connect regulator to the cylinder

6. Tighten left

7. Turn the propane on slowly

8. If propane flow can be heard for more than a few seconds, turn off the propane and check all connections and valves
9. Test connection with soap solution
10. If a leak is present turn off propane and retighten
11. Turn on propane and test again
12. If leak cannot be stopped by application of moderate tightening effort, do not use the equipment, return for repairs.

Procedure for Lighting of Heater
1. Have an igniter ready
2. Hold in red button
3. Light
4. Hold red button for about 30 seconds
5. If flame goes out, wait at least 5 minutes before trying to light again

Procedure for Shutting down Heater
1. Turn off the propane at the cylinder
2. Let the flame burn out
3. Disconnect the hose from the Heater.

Procedure for Torch or Burner Lighting and Shutdown
1. Ensure a proper regulator and that the needle valve is closed
2. Connect the propane
3. Turn the propane on slowly and all the way on
4. Check all connections for leaks with soap solution
5. Have igniter ready
6. Open needle valve and light the torch
7. The torch is not to be left unattended unless it is fitted with a flame failure safeguard.
8. To shut down, turn off propane at cylinder first, let the flame burn out and then disconnect hose from torch

5.41.3 Employee Training

All employees, that in the course of their duties, must handle propane for any equipment operation, shall be fully trained and certified in the safe handling and use of propane bottles, hoses, regulators and the implement being powered by propane. Prior to any use of propane powered equipment the employee must pass a Certified Propane training course (ie/ Ontario Propane Association, CSAO etc). Upon successful completion of the course the employee shall be instructed in house in the proper use, inspection and maintenance of propane equipment in accordance with McNally’s program.

5.42 Removing Rock from Teeth of Clamshell Bucket

The importance of wearing proper personnel protective equipment and working safely in this work situation cannot be overstated.
1. The foreman will have the crane operator to try to "work" the rock out of the bucket teeth by continuing the normal dredging operation.

2. If the rock does not loosen after a short work period, have the crane operator set the bucket on its side on the dredge deck.

3. Try to remove the rock using a long pry bar.

4. If this is unsuccessful, try using a chain and a come-a-long to dislodge the rock.

5. As a last resort, try to break the rock with a sledgehammer.

6. Use safety glasses or goggles and leg protection (chain saw pants).

7. Try not to use heavy blows with the sledgehammer in order to reduce the risk of flying particles.

5.43 Roof Support for Rock Tunnel

This procedure details the method of installing a primary roof support in a rock tunnel. This procedure details the two basic support systems utilized most commonly by McNally. One is rock bolts, resin grout cartridges, wire mesh & shotcrete. The other system consists of rock bolts, resin grout cartridges, rolled channels and wood lagging.

Potential Hazards

1. Loose or overhanging rock can fall.

2. Defective drilling equipment.

3. Water & dust from drilling.

4. Air hose breaking causing a whipping action of the hose.

5. Slipping on drilling platform or bottom of tunnel due to water & muck.

6. Shotcrete burns and dust.

7. Injuries from shotcrete rebound.

8. Chemical additives.

9. Injuries from burst hoses and on cleaning of slick line.

Procedures

1. Prior to commencing the drilling cycle, the roof shall be inspected for loose rock & scaled.

2. When a worker is working in a rock tunnel, he should walk as close to the wall as possible to avoid falling rocks.

3. Tunnels & shafts where workers are working must be inspected at least once a shift & scaled & supported as required. The entire tunnel, including roof & walls, must be inspected at least once a day a competent person. Inspection records maintained on the surface. (OHSA Reg.307)

4. Tunnels must be kept reasonably free of water when a worker is required to be in the tunnel (OHSA Reg.308)
5. Install rock bolts as close to face as possible as the tunnelling proceeds. Bolts to be set into drilled holes in rock & fully secured with resin cartridges.

7. Install primary roof support in accordance with contract/shop drawings.

8. Where shotcrete is used with wire mesh, secure wire mesh to rock using plates and rock bolts. Where shotcrete is utilized ensure all personnel are aware of the hazards associated with it. Only trained personnel to operate the shotcrete equipment.

5.44 Scaffolds

5.44.1 Use of Wood Scaffolds

The construction of wood scaffold is closely regulated by legislation. Materials and material dimensions are specified in detail in the Occupational Health & Safety General Safety Regulations.

Because the construction of these scaffolds can vary greatly as to use, shape, location and the type of job to be done, they sometimes are built in a haphazard manner. To avoid this, the following Safe Work Practices are minimum.

1. Construction, alteration, design and removal of any wood scaffold is to be done by competent workers.

2. The material used to construct these scaffolds should be sound, close grained and finished on all four sides.

3. The scaffold must be capable of supporting 4 times the load that might be imposed on it.

4. All component parts should be tight together and properly fixed to each other.

5. Proper perimeter railing must be set in place. Top rail -intermediate rail -toe board.

6. Scaffold work platforms shall be at least 500 millimetres wide for light duty and 1 meter wide for heavy-duty scaffolds.

7. When used as a scaffold work platform, planks shall be secured from movement by cleats or by being wired in place.

8. Safe access and egress is to be provided to all work platforms by the use of ladders.

9. Scaffold work platforms shall not span more than 3.1 metres on light duty scaffolds or 2.3 metres on heavy-duty scaffolds.

5.44.2 Use of Metal Scaffolds

These are various types of metal scaffolds and they all have a right and wrong way to be erected.

The misuse of scaffolding is the cause of numerous serious injuries. Every worker who designs or constructs a scaffold should be competent and know what the manufacturer's specifications are for that type of scaffold.

The scaffold type that will be best suited for the job and capable of withstanding the loads to be imposed on it must be determined before the job begins.
Ensure that:

1. The scaffold you intend to use is the correct one for the job;
2. The location in which the scaffold is to be constructed is level or is capable of presenting secure footing by use of mudsills or some other device;
3. The scaffold will be erected by a competent worker;
4. Legislative and manufacturer's requirements have been complied with;
5. Safe access and egress to both the scaffold and the general work area has been provided;
6. Levelling adjustment screws have not been over extended;
7. Tower scaffolds have outriggers or are guyed and have all component parts secured in place (i.e. cross braces, pins, lateral braces);
8. Scaffold work platforms have perimeter guardrail
   - Horizontal rail - 0.92 metres to 1.07 metres above the platform;
   - Intermediate rail - Horizontal rail midway between scaffold platform and top rail;
   - Toe board - Horizontal member at platform level no less than 140 mm in height above the platform level;
9. Scaffold planks are of number one grade materials with maximum spans of 3.1 metres on light duty and 2.3 metres on heavy duty with a maximum projection beyond the ledger of no more than 300 mm.

5.45 Scows

5.45.1 Operation of Bottom Door Dump Scows

The importance of wearing proper personnel protective equipment and working safely in this work situation cannot be overstated.

1. Always be cautious while working on a dump scow, as the deck is usually wet and therefore slippery.
2. Adverse weather and/or darkness require you to work with extra caution.
3. You should remain inside the scow but while the scow is underway.
4. Maintain periodic VHF radio communication with the tugboat captain.
5. Scowmen and dredge personnel should always check that the receptacles, on the power cord used to supply electricity to wind the scow doors, are clean and dry before attempting to connect them together.
6. Always remember that you are working with 3-phase electrical power of 440 Volt or 550 Volt.
7. Never connect or disconnect a power cord while the switch is in the "ON" position.

5.46 Setting Steel Piles in Driving Frame

Due to the long lengths of material and the heavy equipment required to perform this work, all personnel involved must know what their duties are and work carefully using the required Personal Protective Equipment.

1. Check that the crane is in good working condition.
2. Make sure the crane is setting on a firm and level footing.
3. Make sure all crane cables and sheaves are in good condition.
4. Make sure all slings and hooks are in good condition.
5. Check the pile grip to be sure it is locking and releasing properly.
6. Make sure that the crane hook safety latch is latching properly.
7. Designate a signal person.

5.47 Shaft Sinking

If the shafts are to be sunk through water-laden ground, consideration must be given to the ground water, which if left unchecked will be allowed to flow into the excavation. Prior to any shaft sinking, a detailed analysis of the specific ground will be made and a dewatering scheme or alternative system will be implemented. A Professional Engineer must design the shafts.

Potential Hazards

1. Worker falling down drill holes for piles.
2. Worker being hit by bucket of backhoe or clam when operator cannot see down shaft.
3. Loose rocks & ground falling down shaft & hitting workers.
4. Falling material is being lowered into shaft or being removed from shaft.
5. Ground infiltration when installing liner plate or lagging.
6. Kick back from chain saw when installing lagging.
7. Blow back between liner plates when grouting.

Procedures – Liner Plate

1. Prior to commencement a detailed evaluation of the ground will be carried out and a suitable dewatering scheme or alternative system will be established. This scheme will allow for sufficient draw down time before commencing.
2. Excavation for the shaft will commence with a circular pit, 1.2m to 1.8m deep and larger in diameter than the extrados of the line plate rings. Complete liner plate rings will be pre-built on the ground, and then will be installed in this pit such that the top ring lies above ground level. Ribs will be installed inside all the rings to secure them until the collar has been secured.
3. A concrete or grout collar will then be cast around the outside of the rings.
4. Once the concrete has cured excavation will commence and shaft sinking will continue underpinning each liner plate section as sufficient ground is cleared.
5. When 3 full rings have been completed the leading edge will be fluffed up, before fully grouting the rings. A sand/cement grout will be used for this operation. Depending upon the ground it may be possible to construct more than 3 rings before grouting.
6. Shaft sinking will continue in cycles, building each plate before excavating for the next. In ground it may be possible to excavate for a full ring or more before building plates, however as this leaves a large area of ground exposed and must be assessed at the time.

7. Excavation will be carried out, initially using a backhoe from the surface, followed by a clam attached to the shaft crane. If room allows, a mini excavator may be used within the shaft, loading muck to the centre and removing with the shaft crane. Some hand trimming will be required to fit individual plates.

8. On reaching formation, a shaft sump will be formed and a base slab will be poured.

Procedures - Soldier Pile and Lagging
1. Prior to excavating lagged shafts. Soldier piles will be placed to a depth below formation. These may be driven piles, or depending on the nature of the ground, consist of bored piles with steel piles concreted in place once drilled. A weak concrete will be used to facilitate the installation of the lagging.

2. Pile spacing will generally be around 2 1/2m centers, however this is dependant upon the shaft design.

3. As with the liner plate shaft, an evaluation will be made and dewatering scheme will be implemented as deemed necessary.

4. Once all the piles have been completed, excavation will commence using an excavator, initially a pit will be formed to allow the installation of the uppermost water. At this stage, hand raking will be installed around the periphery of the shaft, tying into the top of the soldier piles.

5. As the excavation proceeds, concrete will be removed from the soldier piles to expose the pile flanges and provide clearance to install the lagging boards. The lagging boards will be sized in accordance with the ground loading expected.

6. Lagging will be installed by hand, trimming boards as required and installing boards as soon as practical after ground is exposed.

7. Excavation will be carried in a series of stages, stopping to allow the installation of walers and struts or tiebacks.

8. Once down to formation level, the structure will be bottomed out and a concrete base slab will be formed. A pump sump will be formed within the base slab.

9. During the course of the project routine inspections of the shaft lagging will be carried out and poor sections of lagging will be reinforced.

5.48 Soundings from Deck of Dredge
1. Have foreman stop crane from claming.
2. Lower sounding chain over front of dredge.
3. Be careful that the sounding chain does not get tangled around anyone's feet or any object on the deck.
4. Always make sure that the deck is clean to reduce the possibility of tripping.
5. During winter operations, clean and salt the deck if required.
6. At night, have a deckhand assist you by shining a flashlight on the sounding chain markings.

7. Take soundings at different locations, across front of dredge, being careful not to lean too far out from the edge of the dredge.

8. When soundings are completed, restore the sounding chain in its bucket.

5.49 Splicing H Piles

Due to the nature of this work many hand, foot and leg injuries can result. Read and observe the Safe Work Practices for Rigging, Hoisting and Hand Grinding Steel.

1. Check the crane and its' cables, sheaves, block, hook, etc. for proper operating condition.
2. Check that each welding machine has sufficient fuel, lube, oil and coolant.
3. Check that all welding leads and ground cables are in good condition.
4. Check that all short stubs and ground clamps are in good condition.
5. Use all appropriate Personal Protective Equipment.
6. Use shields to protect other workers from welding flash.
7. Check that your grinder and grinding disks are in good condition.
8. Inform all workers in your area of the nature of your work.
9. Have a Fire Extinguisher on hand.

5.50 Tiger Torches

Tiger torches, although valuable to a job-site, are sometimes misused in a manner that can make them dangerous.

Tiger torches are only to be used for preheating of piping etc. prior to welding.

1. When a torch is used, an adequate fire extinguisher must be present.
2. Torches are not to be used for heating of work areas or thawing of lines and equipment, etc., when not in use.
3. Ensure that the propane bottles are properly shut off.
4. Fuel lines are to have regulators.
5. Propane bottles shall be secured in an upright position.
6. Inspect the equipment for wear, tear and loose connections each time before lighting.
7. Do not use tiger torch in an enclosed area.
8. Always ventilate combustible gases from area before lighting torch.
9. Do not heat an object that contains or has contained flammable liquids or vapours.
10. Do not leave an operating torch unattended.
11. Do not leave work area until you make certain there is no smouldering or hot material that could ignite.

5.51 Towing Scows

1. Captain and deckhand to check that all equipment on tug is working properly before departure.
2. Captain and deckhand to check towline before departure.
3. Captain to check with dredge Foreman for coordinates from point A to point B.
4. Captain to get underway only after receiving "All Clear Signal" from dredge Foreman.
5. Tow Captain and dredge Foreman to remain in contact via VHF radio while tow is underway.
6. While undertow - All deckhands on boats, dump scows and dredges must wear life jackets.
7. If using split scows, make sure systems are operating properly before departure.

5.52 Track laying

Rail is brought to the TBM via flat car. The lengths are removed from the car and stored in the gantry.

Potential Hazards

1. Worker could be struck by rolling stock as it enters the gantry.
2. Rail could slip from lifting device and strike a worker.
3. Pinch points could trap a worker's hand, fingers or feet while handling the rail.

Procedure

1. Personnel are to keep out of the gantry. No one will enter until the locomotive and cars have stopped and the brakes applied.
2. Once the train has entered the gantry, no one will enter until the locomotive and cars have stopped and the brakes applied.
3. While unloading the rail, car workers will ensure the load is rigged securely.
4. During transfer from flat car to storage racks, no worker will stand under the load. Stand clear to one side.
5. Workers will be alert for pinch points when handling the rail.
6. If impact hammers are used, the air hose must be "snaked" to the hammer with choker cables. Hoses and fittings are to be examined before use and secured.
5.53 Traffic Control

The following procedures have been adapted from the Construction Safety Association of Ontario’s Traffic Control Training Program Manuals.

5.53.1 Requirements for Traffic Control

Qualified personnel must perform all traffic control. Requirements for traffic control are to conform to Federal and Provincial Regulations and the Ministry of Transportation Traffic Control Manual for Roadway Work Operations.

Signallers and flagmen etc must be used in accordance to the Occupational Health and Safety Act. Signallers/Flagmen must be properly trained and receive adequate oral and written instructions. A copy of these instructions must be kept on site. (see Table 17 – “Traffic Control Training”)

Signallers/Flagmen must wear an approved Safety Vest at all times.

Dump trucks are to have an audible back up alarm.

All precautions as outline in Section 67 of OHSA must be taken for Traffic Control. Along with the required training, Table 17 “Traffic Control Training”, must be completed and signed by both the employee and the Supervisor prior to an employee being given Traffic Control duties.

5.53.2 Equipment Required

Personal

1. Hard hat, Canadian Standards Association (CSA) certified, Class B

2. Safety boots, CSA-certified, Grade 1 (green triangle CSA patch outside, green rectangular label inside)

3. Ministry approved safety vest. (OHSA Regulation 62)

4. Eye protection: goggles for windy sites, safety sunglasses for sunny conditions

Stop-Slow Sign (Hand Held)

1. Sign should measure 45 centimetres by 45 centimetres (18 inches by 18 inches) and be made of material having the rigidity of plywood at least six millimetres (one-quarter inch) thick.

2. The pole must be 1.2 metres long (four feet).

3. The STOP side should be reflective fluorescent red-orange with corners coloured black so that the red-orange area forms an eight-sided figure with the word STOP in white letters 15 centimetres (six inches) high in the centre of the sign.

4. The SLOW side should be reflective fluorescent chartreuse with retro-reflective white border and the word SLOW in black letters 15 centimetres (six inches) high in the centre of the sign.
For Traffic Control After Dark

1. Wear a hard hat with reflective tape.
2. Use a flashlight with a red cone attachment as well as the STOP-SLOW sign and carry spare batteries.
3. Place flashing amber lights ahead of your post.
4. Stand in a lighted area under temporary or existing street lighting, or illuminated by lights of a parked vehicle (make sure that you stand fully in the light without creating a silhouette).

5.53.3 Dress for the weather

**Hot Days:** Hardhat, safety boots, shirt and full-length pants are required; insect repellent may also be required in some locations

**Cold Days:** warm layered clothing, especially gloves, boots and hard hats with winter liners.

**Wet Days:** highly visible rainwear - under your vest.

5.53.4 Where to Stand

Stand the correct distance from the work area. Refer to the Traffic Control Person Table below.

**TABLE: TRAFFIC CONTROL PERSON (TCP)**

<table>
<thead>
<tr>
<th>Posted Speed</th>
<th>60 km/h or less, one lane or reduced to one lane in each direction</th>
<th>70 km/h or greater, one lane or reduced to one lane in each direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Traffic Volume</td>
<td>Low</td>
<td>High</td>
</tr>
<tr>
<td>Distance of TCP from work zone</td>
<td>10-15 m</td>
<td>20-30 m</td>
</tr>
</tbody>
</table>

General Guidelines to follow:

1. Do not stand on the travelled portion of a roadway and always face oncoming traffic.
2. Be alert at all times. Be aware of construction traffic around you and oncoming traffic on the roadway.
3. Stand alone. Do not allow a group to gather around you.
4. Stand at your post. Sitting is hazardous because you visibility is reduced and the ability of a motorist to see you is reduced.
5. Adjust distances to suit road, weather and speed conditions.
6. Traffic must have room to react to your directions to stop (a vehicle can take at least twice the stopping distance on wet and icy roads)
7. Stand where you can see and be seen by approaching traffic for at least 150 metres (500 feet).
8. Avoid the danger of being backed over or hit by your own equipment.

One consideration in selecting where the Traffic Control Person is positioned is to maintain a colour contrast between the Traffic Control Person and the background. The Traffic Control Person must be clearly visible to the approaching motorist at all times.

Hills and curves call for three Traffic Control People or some other means of communication. The job of the Traffic Control Person in the middle is to relay signals between the other two.
Once you have been assigned a traffic control position by your supervisor, look over the area for methods of escape - a place to get to in order to avoid being injured by a vehicle heading you way, if for some reason the driver has disregarded your signals. If this should happen, protect yourself by moving out of the path of the vehicle and then warn the crew.

5.53.5 How to Signal

Use the STOP-SLOW sign and your arms to direct traffic.

Hold your sign firmly in full view of the oncoming traffic.

Be sure to give the motorist plenty of warning. Do not show the STOP sign when the motorist is too close. The average stopping distance for a vehicle travelling at 50 kilometres per hour (30 miles per hour) is 45 metres (150 feet). Higher speeds will require even more stopping distance.

When showing the SLOW sign, avoid bringing the traffic to a complete halt. When motorists have slowed down, signal them to keep moving slowly.

When showing the STOP sign, use firm hand signals and indicate where you want traffic to stop. When the first vehicle stops, step into the centre of the road so the second vehicle can see you.

Before moving traffic from a stopped position, make sure the opposing traffic has stopped and that the last opposing vehicle has passed your post. Then turn your sign and step back to the shoulder of the road.

Stay alert, keep your eyes on approaching traffic, and make your hand signals crisp and positive. Coordinate your effort with nearby traffic signals to avoid unnecessary delays, tie-ups and confusion. Do not use flags to control traffic.

In some situations, two-way traffic may be allowed through the work zone at reduced speed, with a traffic control person assigned to each direction. Since motorists can be confused or misled by seeing the STOP side of the sign used in the opposite lane, the signs must be modified. The STOP side must be covered to conceal its distinctive shape and command. This should prevent drivers from stopping unexpectedly.

5.53.6 Communication

Do not be distracted by talking to fellow workers or passing pedestrians. If you must talk to motorists, stay at your post and keep the conversation brief.

When using two-way radios to communicate with another traffic control person, take the following precautions:

- Establish clear voice signals for each situation and stick to them.
- Be crisp and positive in your speech. If you do not understand the message as to have it repeated.
- Test the units before starting your shift and carry spare batteries.
- Avoid unnecessary chitchat.
- Do not use two-way radios in blasting zones.

When two traffic control persons are working together they should always be able to see each other in order to co-ordinate the STOP-SLOW sign. Signals between two traffic control persons should be understood (ie/ if a traffic control person changes the sign from stop to slow or vice versa he/she must inform the other traffic control person by signalling with the sign in an up and down or sideways motion. This will ensure that the traffic control persons co-ordinate their activities accordingly. Two-way radios are the best method for proper communication.
When two traffic control persons are not in sight of each other, a third traffic control person should be stationed who can keep both in view.

5.53.7 Encountering Problems

Remember you have an important job to do but you are not a law enforcement officer.

Report motorists who are endangering the safety of the public or construction workers to your supervisor.

Keep a pad and pencil and write down violators’ licence numbers.

Ask the supervisor for assistance from police in difficult or unusual traffic situations.

Never restrain a motorist forcibly or take out your anger on any vehicle.

You should always be alert to the needs of emergency vehicles. Ambulances, police and fire vehicles have priority over all other traffic.

5.53.8 Preparing for Each Job

Before starting work make sure that you know the following:

- The type of construction you will be involved with - paving, installing pipe, grading, cut and fill etc.
- The type of equipment to be used, such as scrapers, trucks, compactors, graders etc.
- How the equipment will be operating ie/ crossing the road, moving along the shoulder, in culverts etc
- Whether you will have to protect workers setting up components of the traffic control system such as signs, delineators, cones and barriers
- Any special conditions of the contract governing road use
- How public traffic will flow (ie/ along a two-lane highway, around curves or hills, by detour, on a road narrowed to a single lane)
- Before starting each day ensure that the STOP-SLOW sign is clean, undamaged and meets height and size requirements
- Place the "Traffic Control Person Ahead" sign at an appropriate distance to afford motorists adequate warning
- Remove or cover all traffic control signs at quitting time or when traffic control is temporarily suspended
- Arrange with the supervisor for meal, coffee and toilet breaks

5.54 Underground Transport/Tramming (Work Procedures)

Underground transport will include the delivery of material to and from the work site. Tramming incorporates the removal of cuttings from the TBM.

Potential Hazards

1. Personnel can be struck or run over by moving cars.
2. Brake failures or other mechanical malfunctions can lead to an uncontrollable runaway.
3. Possibility of excessive build up of dangerous gases from the diesel emissions (if diesel used)
4. Pinch points occur at all couplings and on trailing gear. Hands, legs or even a whole worker may be trapped.
5. Material may move and create an unstable load.
6. Possibility of fire.
7. Cars may derail due to excessive speed or poor track conditions.

Procedures
1. Procedures have been developed to outline the precautions with respect to rolling stock in the tunnel.
2. A signal light at the portal entrance will warn pedestrians that rolling stock is either in the tunnel or has exited. Signal light controlled by pit bottom man or deck man.
   RED - DO NOT ENTER
   GREEN - ENTER WITH CAUTION
3. Cautionary lights on the gantry will allow the Segment Hoist Operator to control the movement of the segment cars into the unload area (if required)
   RED - STOP
   GREEN - PROCEED WITH CAUTION TOWARDS FACE
   AMBER - PROCEED WITH CAUTION AWAY FROM FACE
4. At the beginning of each shift, the locomotive operator will test all braking systems, lights and audible signals. If any deficiencies are noted, the problem(s) will be rectified by the mechanical crew.
5. All personnel will be instructed to recognize the locomotive signals. Workers will be instructed to keep clear of the gantry interior, except when given specific job instruction to work in the gantry.
6. All workers will wear reflective marked clothing or vests when in the vicinity of the rolling stock.
7. Before being left unattended in the tunnel, the operator of the locomotive will:
   • Shut down.
   • Leave controls in NEUTRAL.
   • Apply brakes.
8. A hand held fire extinguisher, minimum 10 lbs ABC will be installed on the locomotive for use in the event of a fire.
9. Specifications for locomotive and ventilation system will be submitted to Department of Labour for approval. (for diesel locomotive only)

<table>
<thead>
<tr>
<th>Diesel Emissions Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>Carbon monoxide (at operator cab)</td>
</tr>
<tr>
<td>Carbon monoxide (at exhaust)</td>
</tr>
<tr>
<td>Nitrous dioxide</td>
</tr>
</tbody>
</table>
10. All diesel locomotives in tunnel will have a fire suppression system on them (if required).
11. If the track ties interfere with the invert being used as a travel way, then a solid walkway at least 300 mm wide will be provided.
12. Safety platforms will be installed at 60 metre intervals if walkway is at track level.
13. Material will be securely fastened before being moved underground.
14. Personnel are not permitted to ride between any of the cars on the train. In the event of a tunnel emergency, an empty muck car may be used to evacuate personnel. They must sit or kneel in the car.
15. All personnel will be made aware of pinch point locations on the cars.
16. If a worker is required to work between the cars, then the locomotive driver will bring the loco to a complete stop. Upon completion of the job, the worker will stand well clear of the cars before signalling the driver to proceed.
17. Grout and segment cars are secured in place at face by the segment unloading locking device or other method when disconnected from the train.
18. Personnel travelling on foot in the tunnel will turn to face an oncoming train.
19. Inspection of the linkage system and safety cables will be conducted periodically for wearing and damage.

5.55 Unloading of Segments (Work Procedures)

Scope
When unloading segments, ribs and lagging, potential hazards exist.

Potential Hazards
When removing segments with a forklift from flat bed trucks, potential hazards to watch for are:

1. Worker may become trapped between forklift and segments.
2. Segments may become unbalanced.
3. Fingers or toes may get pinched while handling segments.
4. When transporting the load, potential hazards may be:
   • The load may become unbalanced and tip.
   • Worker may be struck by forklift while backing up.

Procedures
1. Clearly defined hand communications must exist between forklift operator and spotter.
2. The spotter is to remove himself once the forks have been positioned. Stand to one side, clear of the load, then signal the forklift operator to test the load for balance.

3. While the load is being lifted, all personnel will stand to one side of the load in

4. Once the load has cleared the flat bed, the load must be lowered to the travelling position before proceeding to the stockpile area.

5. Before starting the forklift, the operator must complete a visual circle check and mechanical check of braking systems and hydraulics. If there are deficiencies that cannot be remedied on the spot, the machine will be shut down until examined by a mechanic. The operator must not run the machine if it does not have the primary and back-up braking systems.

5.56 Ventilation

Ventilation to work spaces must be in accordance to the OHSA Regulation 46 which requires that a project is to be adequately ventilated by natural or mechanical means if:

1. a worker may be injured by inhaling a noxious gas, vapour, dust or fume or from a lack of oxygen; or

2. if a gas, vapour, dust or fume may be capable of forming an explosive mixture with the air.

If it is not practical to provide natural or mechanical ventilation in the circumstances described above then respiratory protective equipment suitable for the hazard will be provided to the worker and is to be used by the worker.

Ventilation equipment is to be inspected and maintained on a regular basis as a part of the monthly site inspection.

5.57 Vibratory Pile Hammer

Due to the heavy equipment being used and the specialization of this work, all personnel must know their duties. Always wear a Life Jacket while working on a pile-driving frame on the water.

1. Check all crane cables and sheaves.

2. Check that the crane hook safety latch is operating properly.

3. Check that the sling on the vibratory hammer is in good condition.

4. Check that the vibratory hammer and all the hydraulic hoses and connections are in good condition.

5. Check the hydraulic oil level in the power pack reservoir.

6. Check that there is sufficient fuel, lubricating oil and coolant in the power pack engine.

7. Before starting work and periodically during the job check that the bolts in the driving frame are tight.

8. Attach (2) two tag lines of sufficient size and length to the vibratory hammer.
### 5.58 Welding and Cutting

#### 5.58.1 General Procedures

Work involving welding, cutting and burning can increase the fire and breathing hazard on any job, and the following should be considered prior to the start of work:

1. Always ensure that adequate ventilation is supplied.
2. Where other workers may also be exposed to the hazards created by welding, cutting and burning, they must be alerted to the hazards or protected from them by using "screens".
3. Never start work without proper authorization.
4. A fire extinguisher must always be located near any welding, cutting or burning operation.
5. Before starting, check work area for combustible material and possible flammable vapours.
6. A welder should never work alone. A fire or spark watch should be maintained.
7. Check cables and hoses to protect them from slag or sparks.
8. Never weld or cut lines, drums, tanks, etc. that have been in service without making sure that all precautions have been carried out and permits obtained.
9. Never enter, weld or cut in a confined space without following confined space procedures.
10. When working overhead, use fire resistant materials (blankets, tarp) to control or contain slag and sparks.
11. Cutting and welding must not be performed where sparks and cutting slag will fall on cylinders (move all cylinders away to one side).
12. Open all cylinder valves slowly. The wrench used for opening the cylinder valves should always be kept on the valve spindle when the cylinder is in use.

#### 5.58.2 Portable Arc Welders

Portable arc welders are a piece of equipment that has to be treated like a vehicle and can not be operated indoors.

1. Be sure the machine is firmly attached to the transporting unit.
2. Check all fluid levels, water, oil and gas to be sure they are at acceptable levels for operation.
3. When fuelling, DO NOT "top off" the gas tank. Gasoline expands as the outside temperature rises, this may result in seepage and an ensuing fire.
4. Do not fuel the machine while it is running.
5. Do a "walk around" to check for damage and leaks. Be sure the radiator and gas caps are in proper working order and securely attached. Any repairs should be done by qualified mechanics or technicians.
6. Make sure all cables are wound securely when transporting and the side covers are kept closed to protect the machine from any damage from external objects and outside weather, as well as to protect the operator and others from the moving parts of the machine.
5.58.3 Torches
Cutting and welding torches are made of soft metal. Never drag the torch by the hose. Keep torch tips clean of grease, oil and slag. Clogged torch tips should be cleaned with suitable cleaning wires, drills or other devices designed for the purpose.

Store equipment in a safe place, preferably in a box made for torch parts, hoses and regulators.
Always use proper fitting wrenches when making connections. Do not use vice grips or pipe wrenches.
For safety, install a reverse flow check valve to prevent dangerous flashbacks.
Do not locate cylinders where they can become part of an electrical circuit. Do not strike electrodes against a cylinder to strike an arc. All portable welding equipment must be properly grounded.
No welding or cutting shall be done in any area where there may be flammable materials, explosive gases or vapour without AUTHORIZATION FROM SUPERVISOR.
A fire extinguisher must be close by when welding or cutting.

5.59 Work boats (Getting on and off)

Personal Protective Equipment required
- Protective Headgear
- Protective Footwear
- Life Jacket

Work boat must be securely tied to a wharf or mooring, preferable at a ladder location.

Acknowledgement from Captain that the boat is ready for boarding or loading.

All hands accounted for by the Captain before leaving dock or dredge and located in a safe area of cabin or on deck.

Avoid all horseplay at all times.

Avoid all unnecessary movement while boat is underway.

5.60 Working Alone

Ideally, no worker should be working anywhere alone for any reason. This should be avoided if at all possible. Working alone is not allowed in confined spaces for any reason. When a person must enter a confined space than proper confined space procedures found in this safety program must be complied with as per the Occupational Health and Safety Act section 246.

When there is no alternative and a worker is going to be working alone on a jobsite, the supervisor and the employee must set up a means of communication and establish how frequently they will
communicate. At a minimum the supervisor must communicate with the employee once per hour. On
job sites where workers from other companies are present but no other McNally workers are present this
is not considered to be working alone. Under these circumstances the supervisor must still check in with
the employee 2 to 3 times during the day.

5.61 Working over or near Water

Where a person is exposed to the hazard of falling from a work area located over the water, there is a risk
of drowning. Personal flotation devices shall comply with Standard Regulations.

A personal flotation device shall be worn whenever an employee is working on any vessel (even when it
is docked) and when working near the water within 3m from the waters’ edge. Each employee will be
issued one workvest-lifejacket from McNally’s and it is their responsibility to wear and maintain this
jacket at all times. When the lifejacket is no longer safe to wear it can be exchanged for another one.

The following rescue equipment shall be provided:

1. An adequate motorboat to ensure a safe and timely rescue.
2. A life buoy with 15 metres of polypropylene rope of at least 10 mm in diameter.
3. A boat hook.
4. An audible alarm system to notify of an accident and to, initiate the rescue procedure.

Persons in such numbers, as are needed in the circumstances, to perform rescue operations safely, shall
be available, who are:

1. Designated to perform specific rescue tasks.
2. Properly informed as to the proper rescue procedures.
3. Trained in the use of the rescue equipment.

Where work is being done above water that has a fast current and where practicable, a line shall be
placed across the water.

1. Line is to be 10 mm diameter minimum polypropylene rope.
2. Line is to have buoys or some other flotation device attached.

6.0 EMERGENCY PROCEDURES

A worker who has a basic understanding of the emergency procedures and remains calm has already increased the probability of survival. Every location must have a map of the work place that shows evacuation routes, head count location, first aid station, and fire extinguishers. A map showing the name, phone No. & route to hospital should also be available. This map should be posted near an exit.

6.3 Evacuation Procedure

1. Circumstances may require a complete evacuation of an area due to instances of hazardous chemical spills, explosions or any other type of disaster. These circumstances are remote but possible and therefore all personnel must be familiar with the procedures.

2. All supervisory personnel will be responsible for head counts and will restrict access into the evacuation area except to emergency crews.

3. If required, the Tunnel Rescue Team will be notified along with outside authorities.

4. The Project Manager-Supervisor will notify personnel at the termination of the evacuation and the safe return to normal procedures.
6.4 Explosions

Explosions may be caused by the ignition of certain gases. Two of the most explosive gases are methane and hydrogen sulphide.

**Methane** is lighter than air and if ignited within its explosive range will “fireball” across the crown of the tunnel. If this situation is encountered, put on the self-rescuer and drop flat onto the invert of the tunnel; the fire will consume the oxygen in the area. Once the fire has passed overhead, keep low and stay where you are unless the situation dictates that you have to move.

**Hydrogen sulphide** is heavier than air and tends to accumulate low to the floor of the heading. If ignited, the explosion will again appear as a “rolling fireball” closer to the ground than methane. If there are any indications of hydrogen sulphide or any other explosive gases, be prepared to put on your self-rescuer.

**Precautions:** The risk of an explosion can be reduced if the worker observes rules pertaining to good fire prevention including the reduction of combustible material and flammable liquids, the observance of the “No Smoking” or “No Open Flame” rules, good work practices during welding and cutting procedures (Hot Work Permit) and the testing of the work place if explosive gases are suspected.

6.5 Fire Procedure

If you discover a fire:

1. Notify everyone in the area of the fire.
2. Consider using a fire extinguisher if you believe you can safely put the fire out, otherwise leave the fire area, closing all doors behind you, (if possible). Always using the nearest safe exit.
3. Go to nearest phone and call “911” or the applicable fire department phone number and then notify a supervisor.
4. For using a fire extinguisher use the correct type. Note: **Do not use water or foam on an electrical fire.** Approach the fire with the wind or ventilation at your back. In broad sweeping motions, douse the flames. As you get nearer the fire, narrow down the width of the sweeping motions. Once the flames have been put out retreat facing the fire, have a clear travel way behind you and observe the fire for restarting.
5. Report the incident
6. All personnel not underground will report to the emergency meeting area for Head Count
7. To fight a fire on a Barge or Tug Boat a employee must be trained in Marine Fire Fighting
8. When being requested to evacuate a building or trailer: Stop all work, shut down equipment (if possible) and do not return to pick up your belongings.

6.6 Gas Lines (Break Procedures)

_The following has been adapted from an OSWCA bulletin received Spring 2002._

Any strike of a utility line or pipe should be reported to the utility owner. It is not necessary to actually puncture or break the line to be reportable, any significant strike or loss of structural support that weakens or could result in a line failure must be reported.

1. Be specific about the location of the line hit and whether it is a confirmed break or potential line damage and make a note of the time, date when the line hit was reported as well as the telephone number and/or fax number and name of individual and company to whom the strike was reported.
2. If the line had insufficient coverage (ie less than 12") or if the locate was inaccurate, document with photos if possible.

3. The Environmental Protection Act requires the report of any spill of a pollutant (ie natural gas) into the natural environment that is abnormal in quality or quantity, and which is likely to cause an adverse effect to the Ministry of the Environment, the local municipality and the owner of the pollutant (utility).

4. To contact the Ministry of the Environment’s Spill Action Hotline – call 1-800-268-6060

5. The Technical Standards & Safety Act requires any size release to be reported to the gas distributor.

6. In determining whether the spill is likely to cause an adverse effect, if gas spill requires an evacuation of residences or other properties, results in closure of roads or facilities or results in a fire or explosion it is likely to or has caused an adverse effect.

7. If in doubt – call.

8. If the utility line hit resulted in injury follow appropriate company procedures. For a critical injury the Ministry of Labour must also be notified immediately and the scene secured.

6.7 Hazardous Materials (Spill Procedures)

A spill is a discharge of a contaminant into the natural environment, from or out of a structure, vehicle or other containers which is abnormal in quality or quantity in light of the circumstances of the discharge.

Spills can be from containers including drums and tanks, motor vehicle accidents, breaks in hydraulic hoses or piping to name a few.

It is the Company’s responsibility to prevent spills but if a spill does occur, it is our responsibility to clean it up, notify the appropriate authority and restore the environment to its original state where possible.

All hazardous materials must be stored and contained as per WHMIS, or other Regulations or local agency having jurisdiction. If a spill is detected, it is to be contained immediately in the safest manner possible. The Project Manager – Supervisor is to be immediately notified and call for assistance if required.

If a spill is detected on the water:

1. An absorbent boom shall be placed downstream of the entry point of the spill.
2. Once the boom contains the spill, it can be pumped into 205 litre (45 gallon) drums or a storage tank.
3. In still or slow moving water, it may be possible to deploy absorbent pads to remove the spilled material.
4. See “Emergency Procedure For Marine Work”, Table 7

6.8 Tunnel Rescue Procedure

This procedure details the rescue crews, rescue procedure and training to ensure each team is able to perform their duty. Copies of the tunnel rescue procedures, signed by the Project Supervisor and Tunnel Superintendent, shall be posted in a conspicuous place on the project.

6.8.1 Rescue Equipment

Draeger Oxy K Plus, oxygen self-rescuer. The unit will provide oxygen to the wearer for a period of 60 minutes whilst walking, and up to 3 hours at rest. These units will be used for self-rescue only.
Draeger BG174 self-contained oxygen breathing apparatus. These units combine a chemical removal of \( \text{CO}_2 \) with the addition of pure oxygen. When fully charged to 3000 psi the wearer is provided with complete protection for up to 4 hours.

All equipment will be kept within a well-maintained safety container located on job site. The equipment will be checked every 30 days with a record of checks maintained.

The container will contain all the safety equipment together with a notice board displaying all the procedures. Additionally a list of the rescue crew will be clearly displayed on the notice board. The list will indicate the names of the Captain and all other crew members.

Draeger rescue sets will be maintained within the container; each unit will be numbered and will be stored on a corresponding storage shelf. Four units will be supplied; it will therefore be necessary to share the units between the rescue teams, if required. Within a team each member will be allocated a rescue set and the nominated rescuer number will be posted alongside the crew member's name.

Stretchers, first aid kits, and blankets will be maintained at the shaft. (Area field office).

An outside telephone will be provided at the top of the shaft area, (site office) to enable the emergency services to be called.

6.8.2 Rescue Teams

Consist of 4 persons, trained in the use of Draeger BG174 self-contained breathing apparatus. A team will nominate a captain. Additionally one member will be responsible for first aid, one member for gas monitoring, one for the fire fighting equipment and two for the stretcher. All crews will undertake periodic training to ensure each member is fully aware of the system. A team that enters the tunnel will have no less than 4 persons.

A tunnel rescue team is required to rescue workers when a toxic gas or fire exists underground.

In the event of an emergency below ground, an assessment will be made by the person in charge as to the severity of the incident and the necessity for the rescue team. If any doubt exists about the incident the current rescue team will be mobilized.

Following commencement of the tunnel, a trial rescue will be carried out, to familiarize all crew members with the procedure. Once tunnelling is underway, a training session will be set aside once per month for each rescue team. The training will include entry into the tunnel (when practical), practice with the stretcher and use of the breathing apparatus.

Procedures

Prior to commencement of the tunnels the rescue crews will be chosen, initial training will be carried out and a list of each crew will be posted on the site notice board. Contact numbers will be provided against each of the crew members.

When called the rescue team will assemble in the safety room. The first member to arrive will arrange the rescue sets, fire equipment, first aid kits and rescue equipment such that every item is readily on hand. On arrival of all members, the Captain will take over and will issue the orders to field test the rescue sets. The sets will each be tested by the crew member allocated to that equipment. On completion of the test the sets will be donned by each member, the units will not be turned on at this stage, face masks will be slung around each person's neck.

The spare rescue set, stretcher, extinguishers, first aid kit and gas monitors will be checked and transported by the crew.

The team will move from the safety container to the shaft. The incident will be reassessed, before making entry into the tunnel. Depending upon the nature of the incident it may be necessary to put on face mask and turn on air prior to entering the shaft, additionally the method of entry into the shaft may vary, with access either by the shaft man-way, or by crane lift man cage.
A safe area will be established either in the base of the shaft or at the surface, this will be referred to as the fresh air base (FAB). All communications to the rescue team will be handled from the FAB. An incident surface controller will direct operations from the surface. The surface controller will be responsible for directing all operations until such a time as the emergency services arrive and take over. The plan for the rescue will be discussed between the Rescue team and the incident controller, prearranged check-ins will be arranged whereby the team captain is to report back to the incident controller.

On leaving the FAB for the tunnel the rescue team will turn on the breathing apparatus, don the masks and check the equipment. The Captain who will make a note of the checks including each member’s cylinder pressures will direct all actions. Throughout the rescue, checks will be made by the captain of each member at 15 minute intervals; again these checks will be recorded. Additionally throughout the tunnel the captain will check back to the surface controller at predetermined locations. Entry will be made by Locomotive and/or gurney car as far as possible, or until smoke is reached. The gurney car may be taken forward through the smoke to the accident scene should conditions allow.

On arrival at the incident scene, the team Captain will make an assessment. Any necessary first aid will be given, fire will be controlled as required to facilitate the rescue. The rescue team will carry out no fire fighting over and above what is required to facilitate the rescue.

All trapped persons within the tunnel will be located. Any able-bodied persons will be asked to don their self-rescuers if they have not already done so. Injured persons will be treated and placed on the stretcher. Should more than one person be injured, multiple trips may be required. The most serious injured will be removed first. No crewmember would be left behind unless conditions were sufficiently severe to warrant this. The whole team will leave the tunnel keeping all other people ahead of the last man in the rescue team. (Alternately, transport of workers may be required by stretcher or locomotive). No persons wearing self rescue sets are to assist in the rescue. They are to rescue themselves only.

Persons will be lifted from the shaft if necessary by means of the stretcher with a lifting bridle fitted to the crane, or by safety basket.

On completion of the rescue, with all members back at the FAB, breathing sets will be removed and the team will return to the rescue container. A report is to be completed by the team Captain while the information is still fresh in the mind.

No further entry into the tunnel is to be made prior to a full assessment by the Project Supervisor.

6.9 Emergency Procedure for the Rescue of an Underground Worker

Procedures

In the event of an emergency below ground, an assessment will be made by the person in charge as to the severity of the injury and the appropriate rescue equipment & procedure.

For an injury below ground the following steps will be taken:

1. A competent person, fully trained in first aid will take charge of the situation.
2. Call for assistance from fellow workers.
3. Assess the hazards at the scene; make the area safe for yourself and others.
4. Identify yourself to the casualty as a first aider and offer assistance.
5. Quickly assess the casualty for life threatening conditions. (ABC)
7. Send another person to notify the office on dayshift, or the deck man on night / afternoon shift. Notify them, using the tunnel telephone. Giving the following information.
• Your Name
• Name of injured person
• Location of incident
• What the injuries are to the best of your knowledge
• If 911 services are required
• Any special equipment required, such as stretcher, backboard, splints, additional first aid equipment etc., to be brought into the tunnel.

8. If Paramedics are required at the scene of injury, make arrangements for their transport by Locomotive. Additionally, ensure free access to the shaft top is maintained for the emergency services and send a person to the site gate to direct the ambulance to the shaft.

9. If injured person is capable of walking, send another person with the injured worker to assist him out of the tunnel.

10. If the injured person requires a stretcher, gurney or locomotive, send a person ahead to assure the track is clear for free passage to the shaft.

11. If an ambulance is not required make arrangements for a pick up to be available at the shaft top to transport the person to the office, or Hospital, depending on the injury.

12. Should the accident involve a fatality or critical injury, the MOL shall be notified immediately. Additionally, the accident scene must not be interfered with or disturbed. Nothing at the scene shall be destroyed, altered or carried away, except that required to assist the casualty, until the MOL Inspector gives permission.

6.10 Emergency Procedure for Marine Work

The following Procedures are to be initiated, where appropriate.

6.10.1 **EMERGENCY PHONE NUMBERS**

911 Fire, Police & Ambulance

M. O. L (416) 235-5330 (Toronto)

Canadian Coast Guard. (Marine Communications & Traffic Services: MCTS)

SARNIA (519) 337-657

PREScott (613) 925-0618

THUNDER BAY (807) 345-4618

DIALING 16 On your Bell Cellular, Cantel or Thunder Bay Cell Telephone.

**VHF. MARINE RADIO CHANNELS**

Channel 16 Distress, Safety & Calling.

**HAND HELD PORTABLE RADIOS**

Position 1 CH7A 156.35 MHz Marine Construction

Position 2 CH16 156.80 MHz Distress, Safety, Calling

Position 3 CH21B 161.65 MHz Weather – Listen Only.
6.10.2 Rescue Equipment: (On Barges & Tugs)

1. Rigid stretcher unit, complete with securing harness, neck brace and lifting attachments.
2. Dedicated Fire Extinguishers, (As required by CCG. Regulations).
3. Dedicated first aid equipment.
5. A first aid kit, blankets, fire extinguisher, stretcher & Confined Space Entry Equipment will be maintained on the Working Barge.
6. An outside telephone for calling emergency services will be maintained.
7. A suitable boat, equipped with a ring buoy attached to fifteen metres of polypropylene rope that is 9.5 millimetres in diameter, a boat hook, a life jacket for every person in the boat. The boat shall be power driven if the water is likely to be rough or swift.
8. An alarm system: boat whistle, bell, horn, or ship to shore radio and an Oil Spill Kit.
9. Immersion Suits, Life Jackets, Inflatable Life Raft, Distress Signals (Flares): List depends on vessel size, type & area of operation, as required by CCG. Regulations.

6.10.3 Medivac

In the event of an injured person, an assessment will be made by the person in charge as to the severity of the injury and the necessity for outside assistance, if outside assistance is required, give the following information:

- Your name.
- Name of injured person.
- Location of incident.
- What the injuries are to the best of your knowledge.
- If 911 services are required.
- Any special equipment required, such as stretcher, backboard, splints, additional first aid equipment etc. to be brought to the barge.

For an injured worker the following steps will be taken:

1. A competent person, fully trained in first aid will take charge of the situation.
2. Call for assistance from fellow workers.
3. Assess the hazards at the scene; make the area safe for yourself and others.
4. Identify yourself to the casualty as first aid person and offer assistance.
5. Quickly assess the casualty for life threatening conditions. (ABC).
7. If Paramedics are required at the scene of injury, make arrangements for their transport by boat, and send a person to direct ambulance to the boat.
8. If injured person is capable of walking, send a person with the casualty to assist him to the boat to be taken to shore.
9. If the injured person requires a stretcher, send a person ahead to insure there is a clear space on the boat to place the stretcher.
10. If ambulance is not required, make arrangements for a pick up to be available at the shore to transport the person to the office, or the Hospital, depending on the injury.

11. Should the accident involve a fatality or critical injury, the MOL shall be notified immediately. Additionally, the accident scene must not be interfered with or disturbed. Nothing at the scene shall be destroyed, altered or carried away, except that required to assist the casualty, until the MOL inspector gives permission.

6.10.4 Man-Overboard

In the event of a man-overboard incident, the following process will be initiated:

1. Sound alarm – 3 long blast on Whistle or general alarm “Bell.
2. Locate and maintain visual contact with person.
3. Deploy life ring, Buoyant life line and self-igniting light
4. Manoeuvre the vessel to permit recovery.
5. Place engines in neutral when next to the person.
6. Effect recovery of person in a safe manner.
7. Administer appropriate first aid. (Follow procedures for MEDIVAC).

6.10.5 Fire

The following should be initiated in the event of a fire onboard:

1. Sound the alarm, continuous ringing of general alarm, horn or whistle.
2. Identify type and location of fire.
3. Contact appropriate shore authorities.
4. If crew cannot put out the fire, remove crew and towing equipment to dock so fire dept can fight fire.

6.10.6 Abandon Ship

The decision to abandon ship is the responsibility of the Captain or senior person onboard, given by verbal command only. The vessel is equipped with life saving equipment applicable to her size and function. The following process should be initiated once abandon ship order has been given:

1. Immersion Suits to be worn when ordered to or life raft is deployed.
2. Personnel to proceed to their abandon ship station.
3. Ensure Raft latches are released.
4. Ensure painter is secured to a strong point.
5. Ensure the water below the raft is clear.
6. Deploy life raft, as boat drill requires.
7. Board raft and manoeuvre clear of vessel.

6.10.7 Procedure for Fuelling Vessels

1. Material Safety Data Sheet to be reviewed by workers handling fuel.
2. The on site storage of bulk fuel is to be restricted to the delivery truck and fuel storage tanks aboard the vessel.
3. Fuelling equipment to be grounded during fuelling operations, Fuel nozzle is grounded to steel vessel that is in the water.

4. Fuel truck to have ABC fire extinguisher.

5. Vessel to be equipped with fire extinguishers.

6. All equipment to be in good working order and free of leaking seals to prevent lubricants from entering the environment.

7. In the event of any chemical spill, immediately notify appropriate authorities.

8. Fuel truck to have hose nozzle with a positive shut-off.

9. Fuelling port on vessel to have a sealed cap.

10. Vessel is equipped with absorbent pads in the event of a minor spill.

11. See Chapter 5 of this Policy and Program for additional instructions on Fuel Handling.

6.10.8 Hazardous Materials Spills

Upon discovery of a hazardous materials spill, personnel will assess the situation to determine the severity, and potential for escalation of the danger. At this point it will be decided whether action can be taken to control the situation using vessel personnel or to request assistance. All spills or suspected spills of hazardous materials, on land or into the water, regardless of size, are to be reported immediately to the Supervisor. The Supervisor will in turn immediately report the spill to the Project Manager or delegate, who shall ensure notification of the appropriate authorities, the Spill Action Hotline of the Ministry of the Environment, phone 1-800-268-6060, unless the spill is classed as non-reportable, according to the criteria below:

1. Non-Reportable Spills

Class VIII Spill: a spill of a fluid petroleum product at a location defined in the Liquid fuels Handling Act as a bulk plant, marina, private outlet or retail outlet, of not more than 100 litres in areas restricted from public access.

Conditions required for a Class VIII spill to be exempt from reporting requirements:

- The spill does not enter and is not likely to enter any waters, directly or through drainage structures;
- The Spill does not cause and is not likely to cause any adverse effects, other than those that are readily remediated through cleanup and restoration of paved, gravelled or sodded surfaces; and
- Arrangements for the remediation referred to in (b) above are made and carried out immediately and
- Records of the spill are maintained.

2. Other Spills

Any spill exceeding 100 litres or which does not meet the conditions for exemption from reporting requirements of the Environmental Protection Act.

Such spills must be reported to the Supervisor, Project Manager and the appropriate Authorities. The report is to include details of the type of material spilled, the source of the spill and whether the spill has reached the environment (ie through drains, sumps or waterways).

The supervisor or other designated person is to take charge of the spill containment and cleanup. Workers are to be assigned to assist with control and remedial measures:

- Stop the leak
• Block off any drains or access to drainage
• If spill has entered or is in danger of entering a waterway, boom-off area to contain spill
• Assess the level of the spill and report as necessary
• Assess the method of cleanup
• In an environmentally sensitive area, get advice from the Ministry of the Environment as to clean-up measures
• Proceed with recovery of spilled chemical and clean-up
• Arrange appropriate disposal of chemical recovered and debris (in landfill site)
• If a government authority sends a representative to monitor the clean-up and to ensure that it is done adequately, cooperate with such representative
• Maintain a record of the spill and cleanup

To facilitate quick response there is to be a record readily available of the spill response equipment on site and its location. The records are to include contact information for sources of spill control, containment and clean-up supplies to augment those on site, if required and names of spill cleanup contractors in the area.

6.10.9 Heavy Weather

The weather conditions will be monitored via the marine weather channel. When heavy weather conditions are predicted the vessels shall make for protected waters or ensure that they are moored in a satisfactory condition to ride out the weather conditions.

The tug designated as the dredge tug shall be assigned the responsibility of safety boat. See Section 27 (3)-(6) of the Occupational Health and Safety Act and Regulations for Construction Projects.

6.11 Emergency Procedures for Office and Shop

The following procedures listed below have been prepared using a combination of similar instructions from Publications concerning Emergency Preparedness published by the Government of Canada and The Canadian Red Cross. These are included within this Policy and Procedure as a guideline for what to do during some specific disasters/emergency situations.

6.11.1 Earthquake

If you are in a building
• Stay inside and keep away from windows
• Get under a heavy desk or table and hang on, if you can not get under something strong, flatten yourself against an interior wall and protect your head and neck

If you are outside
• Go to an open area and move away from buildings and any other structure that could collapse, stay away from power lines and downed electrical wires

If you are in a car
• Stop the car and stay in it avoiding bridges, overpasses or underpasses, buildings or anything that could collapse on you and your car

Post Earthquake Hazards
- Damaged Buildings – Stay out of damaged buildings even if they look alright
- After shocks – stay put
- Water gets cut off – use emergency water from water heater, toilet tank or melted ice cubes
- Power can go off – stay out of elevators
- Loose or dangling electrical wires – stay away from the wires and advise authorities if you are able to do so
- Broken sewer and water mains – advise the authorities if you are able to do so

6.11.2 Evacuation

If you are advised by the authorities to evacuate your workplace, then do so. Ignoring the warning could jeopardize your safety or those that would have to come in to rescue you.

- Before leaving, turn off power, water and gas.
- Should time allow leave a note informing others when you left and where you went, leave in a place that it is likely to be found
- Follow the routes posted by officials, do not take short cuts as they could lead to blocked or dangerous areas, travel carefully and only if absolutely necessary through flooded areas, roads could be washed away or covered in water
- Keep listening to a battery-operated radio for further instructions, emergency crews will be busy helping those who need help, help them by staying out of the way

6.11.3 Flood

- Shut off basement furnaces and any outside gas valves.
- Shut off the electricity. If the area around the fuse box or circuit breaker is wet, stand on a dry board and shut off the power with a dry wooden stick.
- Never try to cross a flood area on foot as the fast water could sweep you away
- Try not to drive through flood waters as the fast water could sweep your car away. However, if you are caught in fast rising waters and your car stalls, leave it and save yourself and your passengers.

Post Flood Hazards

- Foundation Damage – check for foundation damage prior to re-entering the building, use a flashlight to check for damage, do not strike a match or use an open flame unless you know for certain that the gas has been turned off
- Contaminated Drinking Water – use bottled water or bring water to a rolling boil for 10 minutes minimum
- Basement full of water – drain the water in stages, about a third of the volume of water per day (Draining the water too quickly can cause structural damage to the building)
- Contaminated flood water in the basement – disinfect every three days if the flood is severe and the building is occupied for an extended period. Will need a minimum of 2 litres of liquid bleach to do this.

- **Mould** — Mould is a health hazard, if mould is present wear a face mask and disposable gloves, anything that stays wet long enough will grow mould, dry everything as quickly as possible to avoid future health problems.

**6.11.4 Power failure**

- Turn the thermostat(s) down to a minimum
- Turn off all electronic equipment and tools to prevent injury, damage to equipment and fire when the power returns, power can be restored more easily when the system is not overloaded
- Emergency lighting should come on, wait in an area lit by the emergency lighting for the power to return
- Should a generator be needed always follow the manufacturer’s instructions and operate the generator outdoors in a well-ventilated area away from doors and windows and connect lights etc. directly to the generator, if an extension cord must be used, ensure that it is properly rated, CSA approved cords.

**6.11.5 Severe Lightning Storm**

**If you are in a building**

- Stay inside and away from windows, doors, radiators, stoves, metal pipes, sinks or other electrical charge conductors
- Unplug computers, clocks, photocopiers and other electrical appliances/equipment and do not use the phone or other electrical equipment

**If you are outside**

- Seek shelter in a building but if you are caught in an open area, crouch down with your feet close together and your head down, do not lie flat, try to minimize your contact with the ground to reduce the risk of being electrocuted by a ground charge
- Keep away from telephone and power lines, fences, trees and hilltops
- If you are on a piece of equipment get off it as quickly as possible unless the equipment has been struck by lightning and then stay in the equipment until emergency crews can come to your aid

**If you are in a car**

- Stop the car and stay in it, do not stop near trees or power lines that could fall

**6.11.6 Tornado**

**If you are in a building**

- Go to the basement immediately
- If there is not a basement, crouch or lie flat (under heavy furniture) in an inner hallway or small inner room or stairwell away from windows
- Stay away from large halls, arenas, shopping malls etc (their roofs could collapse).

**If you are outside**

- If there is no shelter, lie down in a ditch or ravine, protecting your head.
- Get out and away from the car, it could be blown through the air or roll over on you
- Lie down in a ditch or ravine, protecting your head

6.11.7 After a major disaster

Right after the emergency, you may be confused or disoriented. Stay calm and remember the following procedures:

- Help the injured, make sure that all employees are accounted for, try to find any that are not
- Listen to the radio on a battery-operated radio for instructions
- Do not use the telephone unless absolutely necessary as emergency crews will need all available lines
- Check buildings for damage
- Use a flashlight not matches if electrical lighting is not available
- Check for fires, fire hazards or other hazards
- Sniff for gas leaks starting at the water heater and if you smell gas, turn off the main gas valve opening windows and doors and get everyone outside quickly. Shut off any other damaged utilities
- Clean up spills using protective clothing, for major spills you may need to call in professional help

6.12 Electricity (Emergency Procedures)

6.12.1 Power line Contact Procedures

1. Stay on the equipment - Generally it is safe for the operator to stay on equipment in contact with a power line as long as the operator does not touch the equipment and the ground at the same time.

2. Keep others away - Warn everyone not to touch the equipment or its load. This includes buckets, load lines, outriggers and any other part of the machine. Warning - Beware of time-delayed relays. Even after line damage taps breakers, relays may still try to restore power up to two or three times - if possible, break contact by moving the equipment clear of the wires.

3. Call Hydro - Get someone to call the local electrical utility company for help. Unless there is fire or imminent danger, stay on the equipment until the utility shuts down the line and confirms that the power is off or the equipment has been moved clear of contact.

4. Emergency Exit - should an emergency such as a fire force you to leave the machine, jump clear, if part of your body contacts the ground while another part touches the machine, current will travel through you. To avoid this jump with feet together and shuffle away in small steps. Do not take big steps. With voltage differential across the ground, one foot may be in a higher voltage area than the other and the difference could kill you.

5. Report - Report every incident of power line contact so that the utility company can check for damage that could cause the line to fall later.

6.12.2 Person in Contact with Electricity

1. In some electrical accidents, the injured or unconscious person remains in contact with the live wire or equipment. Rescue should only be attempted after power has been turned off.
2. In some cases of low voltage, when power cannot be turned off, break contact if possible using a dry board, rubber hose, or dry polypropylene rope to move either the injured person or the line. An object can sometimes be thrown to separate the injured person from the wire.

3. If you do not know the voltage, treat it as high.

4. Even with dry wood or rubber, touching the injured person can be dangerous. High voltage can jump a considerable gap and objects that are normally insulators may become conductors.

5. Call emergency services and give first aid only after the injured person is free of contact.

6.12.3 Electrical Fires

1. Never put water on fires in live electrical equipment or wiring. Water is a conductor and increases the risk of flash, arc, and electrocution.

2. An electrical fire in a contained space can rapidly deplete oxygen and may release toxic fumes. If possible switch the power off, avoid inhaling fumes and vacate the area at once, if necessary breath through a damp cloth and stay close to the floor.

3. Use a Class C or an ABC fire extinguisher.

4. Report Fires to your supervisor immediately.
7.0 FIRST AID AND MEDICAL CARE

7.1 First aid and medical care

7.1.1 First aid station

7.1.2 Regulation 1101 (Brief outline of Contents)

7.1.3 First aid logs/records

7.2 First aid training

7.3 Heat Exhaustion

7.4 Skin Irritants and Rashes

<table>
<thead>
<tr>
<th>Date of this Update</th>
<th>Supersedes</th>
<th>Revision #</th>
<th>Next Review</th>
<th>Update Authorized by</th>
</tr>
</thead>
</table>

7.1 First aid and medical facilities

7.1.1 First aid station

An adequately supplied First aid station will be maintained at each workplace as per Regulation 1101 or other federal/provincial requirements, whichever requirement is greater. First aid kits, stretchers and fire extinguishers will be located in strategic locations. Any company personnel issued a McNally truck must keep one small first aid box in their truck with the supplies replenished/replaced as required.

In addition to meeting the requirements for Regulation 1101, all McNally job sites will have the following added to their first aid stations:

- Directions/map to the nearest hospital(s)
- List of emergency contact phone numbers
- McNally accident reporting procedures poster
- 1 copy of the Green Book (Occupational Health and Safety Act and Regulations)
- WHMIS book
- Copy of the company's Policy and Procedures manual

7.1.2 Regulation 1101

Regulation 1101 outlines the first aid requirements for all construction sites. Requirements for the first aid station (as per Regulation 1101) include the following:

- a first aid box,
- a notice board displaying the WSIB poster known as Form 82
- valid first aid certificates of trained workers and
- an inspection card with spaces for recording the date of the most recent inspection of the first aid station.

The first aid station is to be maintained by a qualified first aider working in the vicinity of the station.

This regulation lists the contents required in the first aid box which is determined by the number of employees at a particular site (1-5, 5-15, 15-200 and 200+) For a list of items required in the first aid kit please refer to a copy of this regulation.
7.1.3 First aid logs/records

A separate log for first aid cases shall be maintained by the Health and Safety Co-ordinator. This log shall record all incidents, accidents, near misses, first aid accidents and critical injuries.

All workers are required to report all incidents and accidents immediately to their supervisor and the supervisor will in turn report all incidents and accidents to the Health and Safety Co-ordinator. For medical aid injuries please refer to chapter 10 in this policy entitled “Accidents”.

Prior to starting a job, the local ambulance, fire department and police station should be made aware of the job.

Information regarding first aid incidents will be regularly shared with the jobsite Joint Health and Safety Committee or Safety Representative and all first aid injuries/incidents will be reviewed regularly by management as a part of the hazard identification process.

7.2 First aid training

McNally will endeavour to ensure that there is a minimum of one (1) trained first aider is present at each jobsite, office and shop at all times.

Employees with current first aid must submit a copy to the Health and Safety Co-ordinator for filing and posting. At each jobsite valid first aid certificates will be posted near the first aid box or station.

7.3 Heat Exhaustion

Symptoms of heat exhaustion include:

- Pale, clammy skin
- Rapid/weak pulse
- Complaints of weakness
- Headaches and nausea
- Sometimes cramps in abdomen or limbs.

When heat exhaustion occurs, you should:

- Move victim to a cool place, but protect from chill,
- Have victim lie down with head level with or lower than the body
- Give victim salt water to drink (one teaspoon of salt to one litre of water) if conscious
- CALL A DOCTOR.

7.4 Skin Irritants and Rashes

Due to the diversity of materials used (solvents, acids, alkalines, resins etc) it is quite possible for skin irritation to occur. The following precautions could help to limit these irritations:

- Use gloves and protective clothing to avoid skin contact where possible,
- Wash frequently with soap and water, personal hygiene is very important,
- Clean equipment on a regular basis
- Have a change of clothes to change into after work, prior to going home,
- Report all cases of skin irritations and rashes immediately to your supervisor.
8.0 ORIENTATION

8.1 Employee Orientation

8.2 Work Refusal

8.2.1 Informing Employees of their Right to Refuse Work

8.2.2 Valid Work Refusals

8.2.3 Procedures for Work Refusals

8.3 Drug and Alcohol Program

8.4 Subcontractor Requirements

8.5 Visitors

8.6 Protection of the Public

</tbody>
</table>

8.1 Employee Orientation

All newly hired and newly assigned employees will attend the orientation program prior to working on the job site, in the office or in the shop. The employee orientation program will include:

1. General overview of the project including safety rules (Table 3)
2. Location of washrooms, fire extinguishers, first aid boxes, WHMIS book etc.
3. Personal Protective Equipment (Table 2)
4. Refusal to work policy and disciplinary procedures – get worker to read and sign work refusal section of the Health and Safety Policy (Section 8.2)
5. Joint Health and Safety Committee (if applicable), Tool Box Talks and site inspections
6. Procedures for Accident & Incident reporting, the company wide Back to Work policy, use of “Functional Abilities Form” (FAF) Give worker a copy of the FAPto keep in their lunch box in case of accident. Get them to sign the Back to work policy. (Section 10.2)
7. Worker/Supervisor Fines by Ministry of Labour
8. Emergency/Fire procedures and hazard reporting
9. Specialized training as required including: Confined Space, Lock out, Tag In/Out steps, Fall Arrest, Manne work – Table 7 and WHMIS
10. Zero tolerance for working under the influence of drugs and/or alcohol

8.2 Work Refusal

8.2.1 Informing Employees of their Right to Refuse Work

A worker is to be informed of their right to refuse “unsafe” work during their initial orientation. They should be given a copy of this policy at time of orientation, they should read it, sign that they understand the policy and this signed policy should be kept in their employee files in Head Office.
8.2.2 Valid Work Refusals

Should an employee feel that a particular job they are being asked to perform is unsafe they are permitted by the Occupational Health and Safety Act to refuse to perform this duty. Work refusals must be completed in accordance to the Act (Section 43 subsection 3).

A worker has the right to refuse work where there is reason to believe that any equipment, machine, device or thing the worker is to use or operate is likely to endanger himself or another worker or is in contravention with the Act; or that the physical condition of the workplace or the part thereof in which he or she works is to work is likely to endanger the individual is in contravention of the Act.

8.2.3 Procedures for Work Refusals

The procedures of a work refusal, in accordance with the Act, are:

- Worker perceives the task required is unsafe and reports this to their supervisor
- Supervisor investigates the task with the worker and one (1) of the following:
  1. Health and Safety Representative,
  2. Joint Health and Safety Committee member or
  3. Knowledgeable employee
- Until investigation is complete worker is to stay in a safe place at or near his work station
- If the supervisor feels the task is NOT safe – the situation is to be corrected. If, however, the supervisor feels the task is safe he can assign another worker to do the task if the first worker still refuses but the supervisor must inform the second employee that the first employee refused.
- If there is no one willing to complete the task and the worker has reasonable grounds to believe the work endangers health and safety, then a Ministry of Labour inspector must be called in.
- Worker may be reassigned reasonable alternative work.
- Inspector will investigate in the presence of the worker and provide a written decision.
- Employees can not be reprimanded for an legitimate work refusal

8.3 Drug & Alcohol Program

The objectives of the Company and purpose of this policy are:

1. To maintain a workplace which is completely free of the negative effects of drug/alcohol use.
2. To accommodate and assist, as appropriate, employees who are identified as having a drug/alcohol related dependency or disorder and to implement appropriate corrective disciplinary action up to and including discharge where employees violate this policy.
3. Where discharge is inappropriate, to implement corrective measures and rehabilitative services which will assist employees who have violated this policy to eventually return to work, with the Company being properly assured that the employees will in the future be completely free of the negative effects of drug/alcohol use while on duty.

The rules of this program are:

1. Information obtained under this policy will be disclosed only to those who “need to know”.
2. All employees must report to work in a physical condition that will enable them to perform their duties in a safe and efficient manner free of the negative effects of drug/alcohol use. Employees who violate any provision of this policy will be subject to corrective disciplinary action up to and including discharge.
3. Employees using prescribed medication which may impair their performance of job duties (impair mental or motor functions) must immediately inform their supervisor of this. For the safety of all employees, the Company will consult with this employee and his/her physician to
determine if a reassignment of duties is necessary. The Company will attempt to accommodate the employee's needs however, if reassignment is not possible, the employee will be placed on temporary medical leave until fit for duty by the prescribing physician.

4. Employees are not to refuse testing, they must immediately report for testing as instructed and shall not take steps which can be seen as obstructing or tampering the accuracy of testing results.

5. When employees receive test results indicating a blood alcohol concentration greater than .02 shall immediately be relieved from duty. They will receive a warning and 24 hour suspension. The second time caught the individual will be again warned and be suspended until counselling has been sought. The third incident will be immediate termination of employment.

Identification and EAP Assistance
Supervisors will monitor employees and will address and report any observations that indicate that an employee is using drugs, alcohol in a manner that violates this policy. Where the Company determines that there is reasonable cause to believe that the employee is in violation of this policy, the employee shall be tested for drugs/alcohol as the next step in identifying the problematic use of drugs/alcohol.

The Company will also encourage its employees to take appropriate action to assist themselves or their fellow employees in identifying and addressing drug/alcohol use which impacts on their ability to perform their duties completely free of the negative effects of drug/alcohol use.

The Company will maintain an Employee Assistance Program (EAP) that provides counselling and rehabilitation services to assist employees in overcoming personal difficulties, including drug/alcohol use, affecting their ability to fulfill their responsibilities at work. Employees are encouraged to contact EAP on their own initiative and all such communications will be kept in strictest confidence.

8.4 Subcontractor Requirements
Prior to commencing work on a job Sub-contractor's must submit the following information to the Project Manager/Superintendent who will in turn provide a copy of this information to Head Office:

- Company Safety Policy and Program
- Current Worker's Compensation Clearance Form
- Ministry of Labour's Form 1000 or Notice of Project whichever is applicable (Unless information on the form changes the Form 1000 only has to be submitted once and will cover all work a Sub-contractor completes for McNally International Inc.)
- McNally's Table 4 "Sub-Contractor/Supplier Orientation"

A representative of the subcontractor shall meet with the Workplace Superintendent to discuss plans when operations change. It should be noted that the subcontractor is to review and apply to the job any new amendments to the Occupational Health and Safety Act and regulations.

Clean up of the work site shall be in accordance with the Contract Documents and Subcontractors agreement.

8.5 Visitors
A visitor is anyone not directly employed by McNally, a sub-contractor on the job or an employee of the owner who is directly assigned to the job. Every visitor must first report to the workplace office. This applies to visits to all areas of the job without exception. A visitor safety orientation must be completed that includes a short safety talk identifying hazards. Visitors are required to sign the "Release from Liability Statement" Table 6 and the "Visitor Orientation" Table 5 prior to commencing visit.
All visitors must be escorted by an employee at all times. Visitors are expected to take notice of all instruction given by their sponsor and to follow all site safety rules including the use of required personal protective equipment. (Provided and trained on usage where necessary.)

Emergency procedures and meeting points are to be outlined for the visitor.

For repeat visits an assessment will be made and further instruction given to explain any variance in circumstance. The above process is waived for emergency response personnel.

No photography will be permitted by visitors unless approved by the workplace manager.

8.6 Protection of the Public

Temporary fencing and barricades shall be erected or placed to provide protection to the public and warning signs will be posted. Traffic control measures will be taken as necessary. Controllers will be trained and use required reflective vests and proper signs.
9.0 TRAINING

9.1 Safety Training Program for Employees

9.2 Training Needs Analysis

9.3 Safety Record Cards

9.4 Workplace Weekly Tool Box Talks

9.5 Supervisory Personnel Training

9.1 Safety Training Program for Employees

The purpose of this program is to provide for safety and related training throughout all levels of the organization.

The Company will arrange for, and employees will participate in, all training that is necessary to minimize the loss of human and physical resources of the company.

The Safety Co-ordinator and/or the supervisory personnel will monitor training requirements on each specific project. They will ensure that employees working in potentially hazardous areas or with specialized equipment have and/or receive the necessary training and proper instruction. Also, the Safety Co-ordinator and/or the supervisory personnel will monitor the legislative training requirements (e.g., number of personnel with various types of training, types of training required, etc.) to ensure each project or location complies with all regulations.

Safety training will include, as required, but not be limited to:

- New hire safety orientations
- Job specific training
- Safety training for supervisors and management
- Task and trade-specific training and certification
- Specialized safety and related training
- Tunnel Rescue Team
- Fire Fighting for Marine Work
- Emergency Procedures For Marine Work and sign copy of procedure. (Table 7)
- Personal Protective Equipment (PPE)
- Fire Extinguisher Training
- First aid Training
- Power Line Hazards Training
- Traffic Control
- Travel Restraint System.

When hired, the worker is required to produce all pertinent training certificates and licenses. Copies of the certificates will be made and forwarded to the Safety Co-ordinator for inclusion in the Employee Database. If the individual cannot produce a valid certificate, for a particular training listed as being received, it will not be included as part of the individual’s training records.
The Safety Co-ordinator is to be informed of any new training that an employee receives and a copy of the certificate should be forwarded to head office for filing in the employees personnel file.

9.2 Training Needs Analysis

Corporate training needs analysis will be done by the Health and Safety Co-ordinator, training will be tracked in spreadsheet form. Facilitating the training needed will be done by the Safety Co-ordinator.

9.3 Safety Record Cards

McNally has a “Card” system for recording employees' safety training. Employees are provided with a Safety Record Card after they have been employed with McNally’s for 1 year or more. Cards are updated on a yearly basis and provided to the employee. Employees should keep these cards in a convenient place near where they are working so that they can be easily shown to Senior Management or a Ministry of Labour inspector if requested.

9.4 Workplace Weekly Tool Box Talks

Workplace toolbox talks with the workers will be held weekly for all shifts (as applicable) at all company workplaces to discuss relevant health and safety issues. Discussions/issues detailed at the toolbox talk must be documented on Table 10 and all attending employees must sign this form. A copy of all Tool Box talks Forms (Table 10) must be submitted to Head Office with the original copy remaining on file on the jobsite.

All sub-contractors on a jobsite will be required to either hold their own weekly workplace tool box talks or attend the weekly McNally meeting. If the sub-contractor chooses to hold their own meeting this must be documented each week and a copy submitted to the on site Joint Health and Safety Committee or Health and Safety Representative (which ever is applicable).

9.5 Supervisory Personnel Training

Supervisory training personnel will be provided with all regular training in equivalent to that of their workers (i.e. fall protection, confined space etc.)

In addition to the regular training provided to McNally employees the supervisory personnel will also take part in more in depth training as required and will be provided with Due Diligence Training to aid them in understanding their role with regards to Health and Safety and the Occupational Health and Safety Act and Regulations.

Supervisory Personnel will also be required to attend a bi-annual Health and Safety Meeting which will be prepared for and conducted by the Division Vice-President, the Health and Safety Co-ordinator and other individuals as directed. In these meetings topics relevant to current projects will be introduced and discussed. Job hazards will be discussed and relevant job specific training will be conducted. At the end of each of these meetings there will be time allotted for open discussion where the attendees will be encouraged to bring up any relevant Safety issues that they have.
10.0 ACCIDENTS

10.1 Accidents and Incidents

10.1.1 Accidents

10.1.2 Critical Injuries

10.1.3 Critical Injuries and the Ministry of Labour

10.1.4 Medical Aid Injury

10.1.5 Incident/First Aid Only Situation

10.2 Back to Work/Light Duty Policy

10.2.1 Program Principles

10.2.2 Functional Abilities Forms

10.2.3 McNally Injured at Work Poster

10.1 Accidents

An accident is defined as an unplanned event that causes harm to people or damage to property. There are three categories of accidents. The type of accident dictates how the injury is handled. Depending on the category the accident falls into dictates how it is to be dealt with. The categories are as follows:

1. Critical Injury
2. Medical Aid
3. Non-medical Aid (Incident)

The employer and the supervisor have a legal obligation to take reasonable precautions for the protection of the workers. The employer also has an obligation to notify the right parties and investigate the accident.

For all injuries the most qualified person around should do the following:

1. Assess the situation, take charge
2. The injured worker’s needs come first, arrange transport to medical facility if required
3. Call Emergency Services, Management, Ministry of Labour, Canadian Coast Guard and Safety Representative as required. If emergency vehicles are called, guide vehicles when they arrive
4. See additional steps below for critical injury.
5. Send WSIB “Functional Abilities Form” with employee to the hospital or doctor. Remind employee of our back to work policy.

10.1.2 Critical Injuries

Definition

The Occupational Health and Safety Act (OSHA) Regulation 834 defines a Critical Injury as “An injury of a serious nature that,
- Places life in jeopardy;
- Produces unconsciousness;
- Results in substantial loss of blood;
- Involves the fracture of a leg or arm but not a finger or toe;
- Involves the amputation of a leg, arm, hand or foot but not a finger or toe;
- Consists of burns to a major portion of the body, or
- Causes the loss of sight in an eye."

Critical Injury Steps
1. **Secure and Manage the Accident Scene.** Investigation begins after the injured worker(s) has received medical attention and the accident scene is safe. The scene must be secured to ensure that no evidence is either removed or disturbed. The only exceptions to this are:
   - for the purpose of saving life or relieving human suffering,
   - maintaining an essential public utility service or public transportation system; or
   - preventing unnecessary damage to equipment or other property.
2. **Notify the Appropriate People**
   In the event of a critical injury the following people are to be advised immediately:
   - Superintendent/Foreman on duty who in turn should contact his Superior
   - McNally Health and Safety Co-ordinator
   - Ministry of Labour
   - Canadian Coast Guard (only if accident occurred on water)
   - Emergency Personnel
   - Joint Health and Safety Committee Worker’s Rep.
3. **Allow Safety Rep.(s) to do Investigation and Complete Report (Table 8 – Accident/Incident/ First aid Investigation Report”)**

10.1.3 Critical Injury and the Ministry of Labour (MOL)
The following is the company policy to be used when dealing with the MOL after a critical injury.
1. The MOL is to be phoned immediately. A written report will be submitted within 48 hours.
2. Secure the scene until MOL advised otherwise.
3. Prior to answering any questions or being interviewed by the MOL ask for the following in writing: Written assurance that no charges will be laid against the company or any individual including you prior to consulting legal advice. If this written assurance will not be given, you should immediately notify your supervisor for assistance before answering any questions.
