Land Acknowledgement

The lands and waters on which the Pickering Nuclear Generating Station (PNGS) is situated are within the traditional and treaty territory of the Williams Treaties First Nations, which includes Curve Lake First Nation, Hiawatha First Nation, Alderville First Nation, Chippewas of Beausoleil First Nation, Chippewas of Georgina Island First Nation, Chippewas of Rama First Nation, and the Mississaugas of Scugog Island First Nation.

The PNGS is within the territory of the Gunshot Treaty and the Williams Treaties of 1923. The Gunshot Treaty Rights were reaffirmed in 2018 in a settlement with Canada and the Province of Ontario.

To acknowledge the treaty and traditional territory, is to recognize the rights of the First Nations. It is to recognize the history of the land, predating the establishment of the earliest European colonies. It is also to acknowledge the significance for the Indigenous peoples who lived and continue to live upon it, to acknowledge the people whose practices and spiritualities are tied to the land and water and continue to develop in relation to the territory and its other inhabitants today.

Executive Summary

Pickering Nuclear Generating Station (PNGS) has a mature and robust groundwater monitoring program in place to address the following three primary objectives:

- Objective 1: Monitor changes to on-site groundwater quality to ensure timely detection of inadvertent releases to groundwater;
- Objective 2: Ensure there are no adverse off-site impacts from PNGS groundwater; and
- Objective 3: Confirm predominant on-site groundwater flow characteristics at the PNGS site.

The findings in 2022 with respect to the above objectives are:

- Objective 1:
 - The groundwater data collected from the system structures and components indicate tritium concentrations are consistent with results for previous years and expected fluctuations associated with ongoing operations or represent increases that occur because of the expected migration of tritium associated with historical releases to groundwater and that are limited over time and space.
 - Dissolved iron concentrations in 2022 associated with the East and West Landfill do not present off-site adverse effects.
 - The results for the remediation approach of natural attenuation of petroleum hydrocarbons present in Units 1 to 4 Standby Generators (SG-A), SG-A Overflow area, Units 5 to 8 Standby Generators (SG-B), Emergency Power Generators (EPG), and EPG3 areas are consistent with historical results.
 - The results of hydrocarbons and dissolved iron associated with the Fukushima Diesel Generators do not present off-site adverse effects.
- Objective 2: Tritium concentrations within the site boundary wells and shoreline wells are stable and are within historical ranges. Off-site effects of tritium in groundwater to Lake Ontario are not observed.
- Objective 3: The predominant groundwater flow patterns remain unchanged in 2022 from the recent years' interpretations.

Title: 2022 PICKERING NUCLEAR GROUNDWATER MONITORING PROGRAM RESULTS		

1.0 INTRODUCTION

Ontario Power Generation (OPG), Pickering Nuclear Generating Station (PNGS), has a mature and robust annual groundwater monitoring program in place. The program examines the chemical, radiological, and physical characteristics of the groundwater beneath the site.

The following three primary objectives are addressed by specific objectives detailed in the N288.7-compliant PNGS Groundwater Protection Plan (GWPP) and Groundwater Monitoring Program (GWMP) (Ecometrix, 2020a):

- Monitor changes to on-site groundwater quality to ensure timely detection of inadvertent releases to groundwater; which include Objectives 1 to 4 of the PNGS GWMP (Ecometrix, 2020a):
 - PNGS GWMP Objective 1: Tritium concentrations in groundwater near system structures and components (SSCs).
 - PNGS GWMP Objective 2: Dissolved iron concentrations in groundwater at East and West Landfills.
 - PNGS GWMP Objective 3: Petroleum hydrocarbon (PHC) concentrations in groundwater at SG-A, SG-A Overflow area, SG-B, EPG, and EPG3.
 - PNGS GWMP Objective 4: PHC concentrations in groundwater at Fukushima Diesel Generators.
- Ensure there are no adverse off-site impacts from PNGS groundwater, as described by Objective 5 of the PNGS GWMP:
 - Tritium concentrations in groundwater in Perimeter Wells - monitor tritium in site perimeter wells to establish tritium concentrations at the PNGS site boundaries and to confirm no adverse off-site impacts.
- Confirm predominant on-site groundwater flow characteristics at the PNGS site, as described by Objective 6 of the PNGS GWMP:
 - Hydraulic Head Measurements - provide head measurements in selected monitoring wells to confirm the groundwater flow conditions across the PNGS site and to support the interpretation of constituent migration in groundwater.

The groundwater sampling and monitoring program conducted in 2022 followed the Sampling and Analysis Plan (SAP) for 2022 (OPG, 2022). This report presents groundwater data collected at PNGS for the period from January 1st to December 31st, 2022.

Title: 2022 PICKERING NUCLEAR GROUNDWATER MONITORING PROGRAM RESULTS		

1.1 Summary of Hydrogeological Characteristics at the PNGS

Eight hydrostratigraphic units (HUs) have been identified beneath PNGS through historical assessments. Of the eight HUs, four main groundwater flow systems have been identified for the site:

- Shallow/Water Table (HU 1-3);
- Intermediate Overburden (HU 6);
- Deep Overburden (HU 7); and
- Deep Bedrock (HU 8).

HUs 4 and 5 are not always observed, and where they are observed, are generally thin and are grouped into the shallow groundwater system. The shallow groundwater system is an aquifer, and the intermediate overburden and bedrock groundwater flow systems are considered to be aquitards. The deep overburden groundwater system may represent an aquifer. Groundwater migration into this HU from overlying HUs is considered to be limited due to the low permeability of the till materials in HU 6.

2.0 2022 PROGRAM DESIGN

The groundwater monitoring program design is detailed in the PNGS GWPP and GWMP (Ecometrix, 2020a). The N288.7-compliant 2022 SAP was developed to meet the relevant components of the objectives listed above.

Groundwater quality results are provided in Appendix A.

2.1 Objective 1 Methodology

2.1.1 Tritium Concentrations in Groundwater Near SSCs

In 2022, as per the SAP, groundwater samples were collected from various locations, including monitoring wells, foundation drains, sumps, and groundtubes (91 sampling locations in total). Figure 1 shows these locations. Most of the locations sampled are near the operating reactors. Refer to Section 6.0 of this report for details on the sampling nomenclature used in the groundwater program.

The 2022 SAP specified the sampling locations and frequency (e.g., quarterly, annually) of sampling tritium concentrations in groundwater at each location.

Report

Internal Use Only		
Document Number: P-REP-10120-10050		Usage Classification: N/A
Sheet Number: N/A	Revision Number: R001	Page: 11 of 64
Title: 2022 PICKERING NUCLEAR GROUNDWATER MONITORING PROGRAM RESULTS		

Groundwater samples analyzed for tritium were collected from the following key areas in 2022:

- Unit 1 to 4 Reactor Buildings (RBs);
- Unit 5 to 8 RBs;
- Irradiated Fuel Bays (IFBs) for Units 1 to 4 and Units 5 to 8; and
- Upgrading Plant Pickering (UPP).

Water levels were collected in each monitoring well prior to the collection of samples by OPG technicians. Following measurement of the water level and prior to sample collection, each monitoring well was purged to remove standing water, ensuring that the groundwater collected had a quality representative of subsurface conditions. Collected samples were analyzed for tritium concentrations by the OPG PNGS Chemistry Laboratory.

The groundwater data generated from the sampling program was subsequently analyzed to either support previous conclusions, identify changes in groundwater quality (trends) including improvements, or demonstrate no significant change. Sample results of groundwater tritium concentrations for Objective 1 are presented in Appendix A (Table A-1, Table A-2, Table A-3 and Table A-4).

2.1.2 Dissolved iron concentrations at East and West Landfills

In 2022, one groundwater sample was collected downgradient of both the East and West Landfills, respectively, along the shoreline. Samples were collected by Pottinger Gaherty Environmental Consultants Ltd. (PGL). Samples analyzed for dissolved iron were submitted to Bureau Veritas, a laboratory accredited to ISO/IEC 17025. Sample results at these locations are presented in Appendix A (Table A-5). Figure 2 shows the locations of the two wells that were monitored in 2022.

2.1.3 PHC concentrations in groundwater at Units 1 to 4 SGs, Units 5 to 8 SGs, EPG and EPG3

A monitored natural attenuation program (MNA) was implemented in the SG-A, SG-A Overflow area and SG-B areas in 2011, following remedial activities. MNA programs are long-term because hydrocarbon mass attenuation occurs through volatilization, dissolution and natural microbial degradation processes. Groundwater monitoring results in these three areas have, in the past, been reported under separate cover. The MNA program for these areas was incorporated into the GWMP developed for the site in 2019. Since that time, the results of the MNA programs in these areas are discussed in the annual report (this report) for PNGS.

In 2022, as per the SAP and the GWMP (Ecometrix, 2020a), eighteen groundwater wells were monitored for water levels and petroleum hydrocarbon free-phase product thickness near the U1–4 SGs. If free-phase product was present in the wells, the thickness of the product and depth to water were the only measurements taken. If free-phase product was not present, groundwater samples were collected for analysis of PHCs including benzene, toluene,

Title: 2022 PICKERING NUCLEAR GROUNDWATER MONITORING PROGRAM RESULTS		

ethylbenzene, and xylenes (BTEX), PHC Fractions 1-4 (PHC F1 to PHC F4), and dissolved iron. In addition, sixteen wells were sampled for the analysis of one or more of the following parameters: PHCs, BTEX, and dissolved iron. Groundwater was sampled using low-flow methodology. Samples analyzed for PHCs, BTEX, and dissolved iron were submitted to Bureau Veritas, a laboratory accredited to ISO/IEC 17025. Figure 3 shows the locations of the wells that were monitored in 2022.

Product thicknesses and water quality analytical results for Units 1 to 4 SGs, Units 5 to 8 SGs, EPG, and EPG3 are presented in Appendix A (Table A-6a and Table A-6b, respectively).

2.1.4 PHCs at Fukushima Diesel Generators

Four groundwater samples were collected in association with the Fukushima diesel generators in 2022. Samples were collected by PGL. Three samples were analyzed for PHCs and BTEX and one sample was analyzed for dissolved iron. All samples were submitted to Bureau Veritas, a laboratory accredited to ISO/IEC 17025, for analysis. Analytical results for groundwater quality within the area of the Fukushima Diesel Generators are presented in Appendix A (Table A-7). Figure 4 shows the locations of the wells that were monitored in 2022.

2.2 Objective 2 Methodology

The 2022 SAP included the sampling of monitoring well clusters at the site boundary to confirm that there are no adverse off-site impacts from PNGS groundwater. Boundary wells are located across the entire site in directions upgradient or cross-gradient to the SSCs and provide spatial information on background groundwater quality conditions. Shoreline wells are also monitored downgradient to the SSCs to assess off-site impacts to groundwater quality. Figure 5 shows the locations of the site perimeter wells. Analytical results for monitoring wells sampled at the PNGS perimeter are presented in Appendix A (Table A-8)

The methodology for groundwater collection, analysis, and data evaluation in the perimeter wells was the same as what is described above for the tritium samples collected under Objective 1.

2.3 Objective 3 Methodology

Groundwater flow interpretations for PNGS were first established in 2002. On an annual basis, the GWMP requires that a set of water levels be collected from several groundwater monitoring wells at the site over a short period of time (days). The intent of the program is to verify that groundwater flow conditions, which are the basis for interpreting the migration of constituents in groundwater, have not changed and that OPG continues to have a sound understanding of groundwater flow patterns at the site. In Q4, water level readings were collected from monitoring well locations across the site over a period of eleven days (October 3 to October 14, 2022). The data was subsequently used to calculate the groundwater elevation at each monitoring well. The resulting groundwater elevations and the average daily mean Lake Ontario water levels between October 3 and October 14, 2022 (IJC, 2023) were used to generate groundwater elevation contours, from which groundwater flow directions are inferred.

3.0 2022 PROGRAM RESULTS

3.1 Objective 1 Results

3.1.1 Tritium Concentrations in Groundwater Near SSCs

In 2022, the groundwater data collected from the areas surrounding SSCs at PNGS indicate that tritium concentrations in groundwater have remained, overall, consistent with results for previous years and within the range of expected fluctuations resulting from ongoing operations, or represent the expected movement of historical tritium releases to groundwater. Further discussion is provided in the sections below.

3.1.1.1 Unit 1 to 4 Reactor Building Area Overview

The 2022 groundwater sampling results within the area of Units 1 to 4 are presented in Table A-1 (Appendix A). The majority of the monitoring wells in this area are sampled quarterly. Figure 6 to Figure 8 display the distributions of maximum annual tritium concentrations within the vicinity of Units 1 to 4 area and Units 1 to 4 IFBs in HU 1-3, HU 6 and HU 7.

Key sampling locations are discussed in further detail below, by specific area.

Unit 1 and 2 Area

Tritium concentrations within groundtubes (U1-RBFD-1 to U1-RBFD-3), monitoring wells towards the south-southeast (MW261-25, MW-270-20, MW-273-20, MW-313-40, MW-315-15, MW-320-20 and MW-313-40) and the Vacuum Building Ramp Sump (VBRS) were generally steady during 2022 and consistent with concentrations measured during previous years (excluding those time periods impacted by leaks). A component of the historically identified tritiated plume in groundwater in this area migrates south towards the VBRS, located east of the Vacuum Building (VB), which acts as a hydraulic sink and collects a portion of groundwater in Unit 1 and 2 areas (Ecometrix, 2020b). The tritium plume within shallow groundwater is shown in Figure 9. Tritium concentrations at MW-321-15, located east of the VBRS were within historical range in 2022.

Tritium concentrations decreased from Q4 2021 and Q1 2022 to Q2 2022 at monitoring well MW-234-30, which is located to the northeast of Unit 1 and remained within historical ranges. Groundwater in the area of Unit 1 is also known to migrate north towards the actively pumped Turbine Axillary Bay (TAB) foundation drains and west towards Units 1-4 IFBs (Ecometrix, 2020b).

Graphs 1 to 12 display tritium concentrations over time at groundtubes and select monitoring wells mentioned above, and the VBRS.

Unit 3 and 4 Area

In the Unit 3 and 4 areas, tritium concentrations measured in RB groundtubes, as well as in the monitoring wells located within the Reactor Auxiliary Bay (RAB), were generally stable, or no trends were observed. Tritium concentrations at downgradient monitoring well MW-243-29 located in the RAB fluctuated in 2022, but show an overall decreasing trend.

Graphs 13 to 14 illustrate the results for selected monitoring wells within the vicinity of Unit 3 and Unit 4.

Title:

2022 PICKERING NUCLEAR GROUNDWATER MONITORING PROGRAM RESULTS

Unit 5 Area

The samples collected from the Unit 5 RB foundation drainage groundtubes in 2022 indicate that tritium concentrations in groundwater have been generally steady. No overall increasing trend in tritium concentrations was observed over the last two years for MW-267-17. The tritium concentrations in groundwater at IAD-SU-5 demonstrate an increasing trend however the values remain within a range considered to reflect fluctuations associated with routine operations. Any changes in groundwater quality are adequately observed with the existing monitoring schedule. Groundwater in these locations will continue to be monitored.

Graphs 15 to 21 present data from the Unit 5 RB foundation drainage groundtubes (RBU5-GT-1 to RBU5-GT-4), the U5 MK26 sump, and MW-267-17, respectively.

Unit 7 Area

At RBU7-GT-1, tritium concentrations in groundwater in February 2022 were the highest since 2015, however, concentrations declined over the year and were consistent with the historical average by October 2022. No trend in groundwater tritium concentrations was identified in RBU7-GT-1. Tritium concentrations in groundwater at RBU7-GT-3 are generally stable overall. Tritium concentrations in groundwater at U7-MK-36 and MW-265-12 were within historical ranges and no increasing trends were identified visually. Tritium concentrations at IAD-SU-7 were among the highest measured to date in February 2022, and tritium concentrations in water sampled at this location overall demonstrate an increasing trend, however, the values remain within a range considered to reflect fluctuations associated with routine operations. Any changes in groundwater quality are adequately observed with the existing monitoring schedule. Groundwater in the Unit 7 area will continue to be monitored.

Unit 8 Area

In 2022, tritium concentrations in the Unit 8 TAB Inactive Drainage (IAD) (IAD-SU-8) sump and Unit 8 RB foundation drainage groundtubes were consistent with historical levels and did not indicate any increasing trends. Tritium concentrations at U8 MK42 were similar to previous years. At MW-264-10, tritium concentrations are measured annually. The concentrations at this well overall demonstrate a probable increasing trend, however, concentrations remain within the range of other monitoring wells close to the RBs in this area. Groundwater will continue to be monitored at this well.

Title:

2022 PICKERING NUCLEAR GROUNDWATER MONITORING PROGRAM RESULTS

3.1.1.3 Irradiated Fuel Bay Areas

IFB-A

In 2022, the eastern groundtubes (IFBA-GT-1A and IFBA-GT-2A) showed higher tritium concentrations than IFBA-GT-5A to the west. Concentrations in IFBA-GT-2A are increasing. Monitoring well MW-244-18 in the vicinity of the IFBs displayed an increased concentration in 2022 compared to the concentration measured in 2021 and demonstrates a probable increasing trend. The tritium concentrations within IFBA-GT-2A and MW-244-18 are expected as groundwater in the Unit 1 area migrates towards the Units 1 to 4 IFB-A and TAB foundation drains in addition to the VBRS. The increased tritium concentrations are interpreted as the western edge of the tritium plume associated with the 2020 heavy water release originating in the Unit 1 area, extending towards the IFB-A. Groundwater in the protected area eventually flows north towards the low-lying TAB sumps which are eventually discharged via a monitored pathway.

Tritium concentrations over time for the IFB-A groundtubes and MW-244-18 are presented in Graph 39 to 43. The 2022 tritium sample results are presented in Table A-3. (Appendix A). Figure 13 and Figure 14 also display the annual maximum tritium distributions of Unit 1 to 4 IFBs in HU 1-3 and HU 6, respectively.

Title:

2022 PICKERING NUCLEAR GROUNDWATER MONITORING PROGRAM RESULTS

Graph 41: IFBA-GT-5A Tritium Data

Graph 42: MW-244-18 Tritium Data

IFB-B

The groundwater results collected from sampling locations in the Irradiated Fuel Bay area located between Units 6 and 7 (IFB-B) are described below.

In 2022, tritium concentrations in the western groundtubes (IFBB-GT-1B, IFBB-GT-2B, and IFBB-GT-3B) increased relative to 2021 and tritium concentrations at all three locations show an upward trend since 2019. Monitoring wells MW-171-15 and MW-172-25 located further south of Units 5-8 continued to show tritium concentrations within historical ranges. In addition, tritium concentrations in each of the eastern groundtubes (IFBB-GT-4B, IFBB-GT-5B, and IFBB-GT-6B) demonstrate decreasing trends. A review of the available groundwater flow conditions suggests groundwater moves from Unit 6, beneath the IFB-B area and ultimately towards the TAB IAD sumps. As such, the recent increases in tritium concentrations in the western groundtubes within the IFB-B area are likely related to the elevated concentrations observed in Unit 5 and 6 groundtubes since 2021. Groundwater quality in this area will continue to be monitored.

Tritium concentrations over time for the IFB-B groundtubes and monitoring wells are presented in Graphs 44 to 51. The 2022 tritium sample results are presented in Table A-3 (Appendix A). Figure 15 also displays tritium distributions of the Unit 5 to 8 IFBs in HU 6

3.1.2 Dissolved iron concentrations downgradient of East and West Landfills

In 2022, one monitoring well associated with each of the East and West Landfills was sampled for the analysis of dissolved iron (MW-024-20 and MW-205-35). Concentrations of iron are 1,000 µg/L and 1,900 µg/L and remained within the historical range. Concentrations were below the groundwater numeric evaluation criteria of 3,000 µg/L developed in the PN GWPP and GWMP (Ecometrix, 2020a).

Table A-5 (Appendix A) summarizes the dissolved iron concentrations at the wells associated with the East and West Landfill.

3.1.3 PHC concentrations in groundwater at Units 1 to 4 SG, Units 5 to 8 SG, EPG and EPG3

In 2022, eighteen wells were monitored within the vicinity of Unit 1 to 4 SG (SG-A), SG-A overflow area, and Unit 5 to 8 SG (SG-B). The monitoring wells were monitored for groundwater/fuel oil product levels and sampled for PHC F1 to F4, BTEX, and dissolved iron, where free-phase hydrocarbon product was not present. Monitoring well MW-287-15 was sampled and analyzed for PHC F1 to F4, BTEX, and dissolved iron in Q3. Product was present in that well and the remaining wells in Q1, Q2, and Q4. The 2022 results for PHC product thickness and hydrocarbons in groundwater in these areas were within the historical ranges for each well in recent years.

In 2022, sixteen monitoring wells were sampled for PHC and BTEX within the vicinity of the SG-A, SG-A overflow area, SG-B, EPG, and EPG3. All samples collected met the MECP Table 9 Site Condition Standard (SCS) for non-potable groundwater within 30 m of a water body and industrial/commercial/community land use except for three locations sampled. PHC F2 concentrations exceeded the MECP SCS at MW-146-15, MW-287-15, and MW-282-15. PHC F3 concentrations exceeded MECP SCS at MW-287-15. In 2022, three monitoring wells were sampled for dissolved iron. Iron concentrations exceeded the numerical evaluation criteria at MW-226-22, in the SG-A overflow area.

However, concentrations of PHC F2 from MW-146-15 have decreased compared to historical samples collected as summarized in the MNA report for 2022 (PGL, 2022, tbl. 2). Concentrations of PHC F2 and F3 at MW-287-15 demonstrate a decreasing trend since 2008 and concentrations of PHC F2 at MW-282-15 does not demonstrate a trend using data from 2010 (PGL, 2022, tbl. 2). The localized presence of PHCs and iron at concentrations above the groundwater evaluation criteria are expected in these areas, where remediation using a natural monitored attenuation approach is ongoing.

Table A-6a (Appendix A) summarizes the product thickness and Table A-6b summarizes the PHC, BTEX, and dissolved iron concentrations at the wells associated with the SG-A, SG-A overflow area, SG-B, EPG, and EPG3.

3.1.4 PHC and dissolved iron concentrations in groundwater at Fukushima Diesel Generators

In 2022, three monitoring wells associated with the Fukushima diesel generators were sampled for the analysis of PHCs and BTEX and one monitoring well was sampled for the

analysis of dissolved iron. PHC and BTEX concentrations remained below detection. The dissolved iron concentration remained below the groundwater numeric evaluation criteria of 3,000 µg/L developed in the PN GWPP and GWMP (Ecometrix, 2020a).

Table A-7 (Appendix A) summarizes the PHC, BTEX, and dissolved iron concentrations at the wells associated with the Fukushima Diesel Generators.

3.3 Objective 2 Results

3.3.1 Site Perimeter Overview

In 2022, concentrations of tritium in groundwater within the boundary perimeter wells were low (less than 900 Bq/L) and are considered to reflect background conditions. Shoreline wells MW-164-13 and MW-165-24 are located southeast of Unit 1 and 2 reactor buildings. Shoreline wells MW-225-12 and MW-226-22 are located southwest of Unit 3 and 4 reactor buildings. Shoreline wells MW-183-10 and MW-184-27 are located southeast of Unit 5-8 reactor buildings and the overall site. Shoreline wells MW-222-10 and MW-223-32 are located south of the UPP area. Tritium concentrations from 2022 in these shoreline wells are within historical ranges and are stable. Tritium concentrations in all shoreline wells remain substantively below groundwater evaluation criteria, demonstrating no potential for off-site impacts from tritium in groundwater at PNGS.

Table A-8 (Appendix A) summarizes the tritium concentrations at each of the perimeter wells, and the annual maximum tritium concentrations within HU1-3, HU 6, and HU 7 are in Figure 18 to Figure 20 respectively. Tritium results within the shoreline wells are shown below in Graphs 55 to 62.

3.4 Objective 3 Results

3.1.5 Overview of Groundwater Flow Direction

The groundwater flow directions inferred for HUs beneath the PNGS from hydraulic head data collected in 2022 are consistent with historical interpretations.

In the shallower groundwater table (HU 1-3; Figure 21), the East Landfill (northeast of the PNGS) remains the major local recharge area with groundwater flowing generally from the landfill towards the station buildings to the southwest, and towards the Lake Ontario in the south.

Closer to the reactor units, groundwater flow directions are more complex due to subsurface structures and active pumping in the TAB foundation drains and VBRS. The general groundwater flow direction is interpreted to be south towards the lake, with influence from the pumping activities around the reactors. Groundwater within the vicinity of Units 1 to 4 is inferred to migrate towards the TAB and IFB-A. In the Units 5 to 8 area, groundwater is generally inferred to migrate towards the TAB. The TAB foundation drains collect groundwater and terminate in the TAB IAD sumps associated with each reactor unit. These sumps also collect other station process water. The water collected in the IAD sumps is eventually discharged via a monitored pathway.

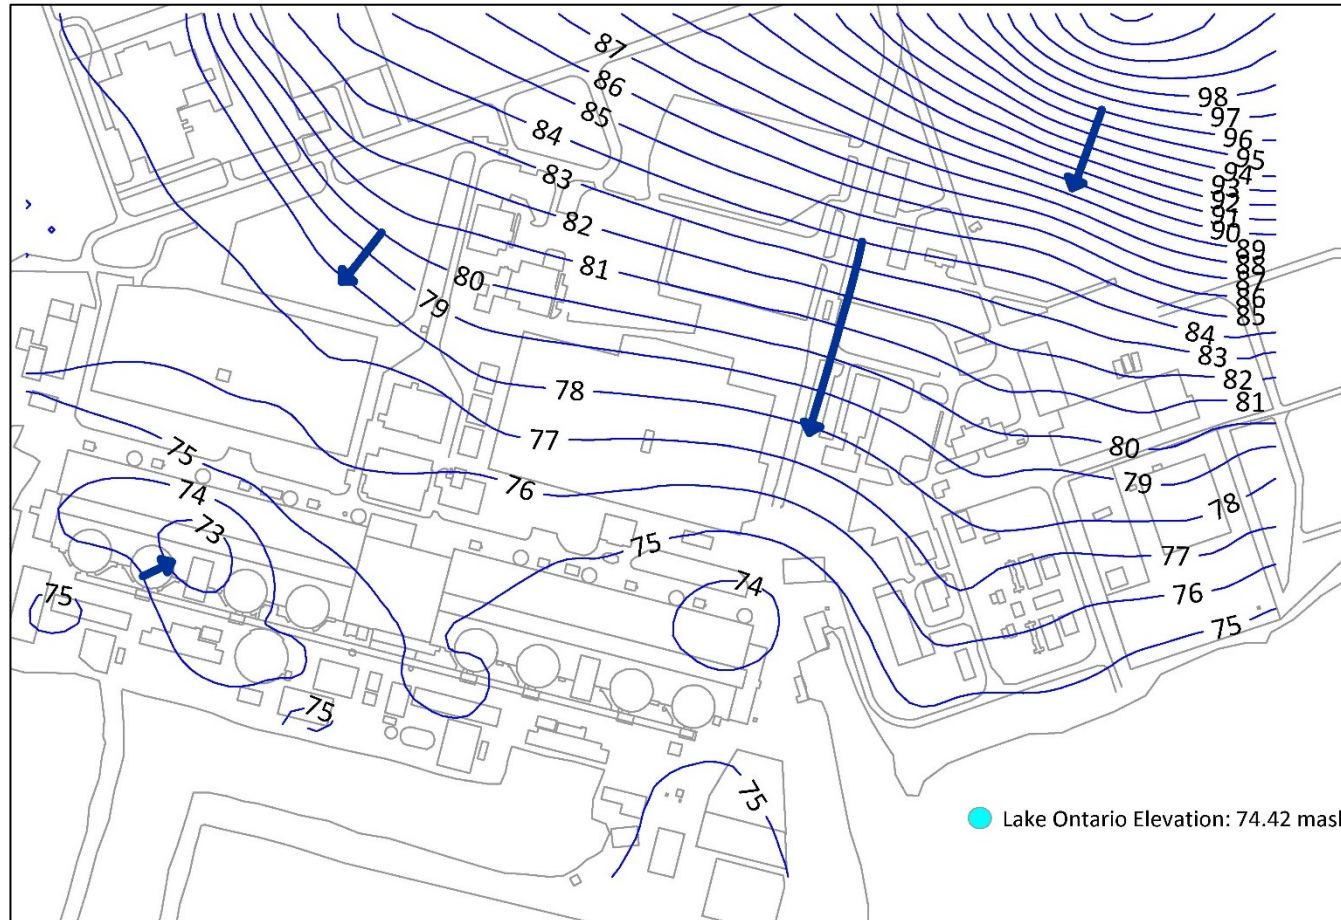

Groundwater within the area of Units 1 and 2 in HU 1-3 is interpreted to migrate towards the VBRS. As mentioned above, the VBRS acts as a hydraulic sink, diverting a portion of groundwater in Unit 1 and 2 areas towards the VBRS.

Water levels collected from wells installed within HU 6 and HU 7 are generally consistent with historical values. Thus, no change in the historically inferred groundwater flow directions in these units, towards Lake Ontario, is suggested.

Overall, the groundwater monitoring completed in 2022 was sufficient to determine groundwater flow conditions at the site and support the understanding of the migration of chemical and radiological constituents in groundwater throughout the site.

Title: 2022 PICKERING NUCLEAR GROUNDWATER MONITORING PROGRAM RESULTS		

Note: Groundwater contours were developed using water level measurements collected between October 3 to 14, 2022. The Lake Ontario elevation used to determine groundwater contours were determined from an average of daily mean water elevations between October 3 to 14, 2022 (IJC, 2023).

4.0 2022 PROGRAM QUALITY ASSURANCE/QUALITY CONTROL

The Quality Assurance and Quality Control measures for the groundwater monitoring program encompass all activities in field sample collection, laboratory analysis, and laboratory quality control. The objective is to provide confidence in the interpretation of the PNGS groundwater monitoring data through a systematic and documented process.

4.1 Quality Assurance Programs for Laboratories

In 2022, samples analyzed for PHC, BTEX, and dissolved iron were submitted to BV, which is accredited to ISO 17025 by the Standards Council of Canada for environmental tests. Many of the conventional contaminants are governed by criteria established in MECP's (formerly Ministry of Environment or MOE) 'Guidance on Sampling and Analytical Methods for Use at Contaminated Sites in Ontario' (MECP, 2009). BV has developed its analytical protocols to meet the recommended analytical protocols documented in this publication.

The PNGS Chemistry Lab performs laboratory activities according to a documented quality assurance program.

4.2 Quality Control Results

Duplicates, field blanks, and trip blanks were collected at a prescribed frequency to measure sampling and analytical performance.

Over the 2022 sampling programs, 42 field duplicate samples were collected. The results and calculated relative percent differences (RPD), to understand the sampling precision, are presented in Table A-9a and Table A-9b (Appendix A). All calculated RPDs were below 20 percent as recommended in the PNGS GWMP. All duplicate samples were deemed of acceptable quality, demonstrating that the field techniques and the analytical methods employed by the laboratories were reproducible and reliable. Quality Control results summarizing Field and Trip Blank samples are presented in Table A-9c (Appendix A).

5.0 SUPPLEMENTARY STUDIES AND AUDITS

There were no supplementary studies initiated or completed in 2022.

6.0 NOMENCLATURE OF SAMPLING LOCATIONS

Sampling Location Type	Identifier	Explanation of Nomenclature
Monitoring Well	MW-XXX-YY	XXX represents a unique identifier YY represents the depth of the monitoring well in feet
